

Income Inequality, Local Taxation, Education and
Voting Behavior
Evidence from France, 1968-2017

Abstract

This study documents the long-running structure of the political cleavage in France over the last fifty years, by focusing on the correlation between education, income, local taxation and voting preferences at the local level. We built long-term series of historical data from French censuses, electoral results, local taxation records and income distributions at the level of nearly 3,500 *cantons* and 36,000 *communes*, a much more disaggregated level of analysis than most of the literature on the political and economic legacy of political cleavage in France. We show that both *cantons* and *communes* in the top income (for the 1993-2017 period) and local tax ratio deciles (for the 2002-2017 period) tend to significantly vote more for right-wing parties than those in the median decile, and less for left-wing parties. Between 1993 and 1997, the education effect goes in the opposite direction, since *cantons* and *communes* in the top education deciles in terms of university graduates vote more for left-wing parties and less for right-wing parties than *cantons* and *communes* in the middle of the distribution. Interestingly, education seems to have the same impact as income for the 1968-1988 period, when we do not control for income because of the lack of available data: this suggests that the effect of income would have been the same for this time period as for the subsequent years. This might show that university graduates did not have the same voting habits in the 1960s-1970s and today (which would corroborate Piketty's finding (2018)).

Keywords: local taxation, income inequalities, education, voting behaviors

JEL Classification: J12, N34, Z130

Acknowledgments I would like to thank Thomas Piketty, my supervisor, for his guidance throughout the elaboration of this study. I also thank Gilles Postel-Vinay for accepting to be referee and for having advised me through the search of historical data on education and income. I am grateful to Julia Cagé for having supervised the data collection of the electoral results, for having shared some of her own datasets, and for her classification of political parties. I thank Nicolas Sauger and Eric Dubois for sharing 1968-1988 election data, and Frédéric Salmon for his work on the geographical and administrative evolution of French *cantons* throughout the time period of interest. Finally, I am obliged to Etienne Pasteau, Florian Bonnet and Aurélie Sotura for their advice regarding census and income data collection.

1 Introduction

What are the immediate and long-term political effects of socio-economic factors on voting behaviors? How do socio-economic inequalities lead some individuals to vote for the extreme political trends, and other rather to choose the pragmatic and classical view of the traditional parties? Since the 18th century, the literature on political cleavage in France has shown the relevance of socio-economic and socio-demographic factors on voting behaviors, such as age, gender, education, occupation and income. However, most of the past and recent studies rely on selected samples from post-electoral surveys or focus on limited time periods. Hence, this paper attempts to further explore the standard electoral theory by constructing new consistent long-run series of electoral results at the municipality and the *cantons* level (the second smallest administrative division of France) for the 1968-2017 period, allowing for a systematic study of the changing political cleavages in France over this period.

This paper builds upon a significant literature on the evolution of political behaviors depending on several socio-economic factors, such as geographical and cultural determinants, education, occupation, income and wealth. The seminal contribution of Siegfried (1949) in the Third Republic France inaugurated the very first national work in spatial politics, by analyzing the persistence of voting behaviors in Western France at a local level, depending on several factors, such as the structure of the land property, religion and geographical conditions. This pioneering study paved the way to subsequent local monographies, such as the analysis of the French Alps (Hugonnier, 1954) and of the Bouches-du-Rhône region (Olivesi and Roncayolo, 1961). More recently, Viskanic and Vertier (2018) analyzed the effect of migration, by studying the relocation of migrants from the Calais ‘Jungle’ to migrant centers, and its effect on the 2017 presidential elections at a municipal level. They

show that the presence of a nearby center reduces the vote share for the extreme-right party.

Regarding socio-economic determinants of voting behaviors, Lipset-Rokkan (1967) stressed the fact that upper social classes are generally in favor of less state intervention, lower wages and taxes. More recently, Nadeau and al. (2012) focus on income as a significant predictor of contemporary voting behaviors. They show a positive correlation between income and the center-right vote, and a negative relationship between income and the extreme-left vote in the French presidential elections between 1988 and 2007. Moreover, by focusing on post-electoral surveys in France, Britain and the United States of America, Piketty (2018) shows that the top 10% (and especially the top 5% and top 1%) income decile is also more likely to vote for the right-wing parties than the bottom 90% of the income distribution, a fact that Pasteau (2018) also shows in his study at the département level. Voting habits seem also to depend on wealth, since voters in the top wealth deciles systematically vote more for right-wing parties than voters in the middle or in the lower wealth deciles (Piketty, 2018).

However, as social stratification declines over time, occupation and education might also play a great role to explain voting behaviors (Cautrès and Mayer, 2004). Goux and Maurin (2004) show that occupation was a predominant explanatory variable for the vote for the Maastricht referendum in 1992, especially for the right-wing parties at the municipal level. More generally, Cautrès and Mayer (2004) point out the positive correlation between extreme-right voting preferences and low education. Finally, Piketty (2018) shows that, while high education was correlated with a right-wing vote in the 1950s-1960s period, a reversal occurred in the 1980s-1990s, leading to highly educated individuals now rather voting for the left.

Finally, this paper forms part of a broader perspective in terms of political cleavages. Modern democracies are shown to face several types of political conflicts across

various dimensions, such as center vs periphery, state vs clerical leadership, agriculture vs manufacturing, working class vs owners, universalist vs traditionalist or liberal vs communitarian (Lipset-Rokkan, 1967, Bornshier, 2010). These moving cleavages change voting behaviors over time: for instance, Piketty (2018) reveals the emergence of an intellectual elite (Brahmin left) in the US, Great Britain and France at the end of the 20th century, who votes more for the left-wing parties, *versus* a business-oriented elite, who votes in favor of the right-wing parties. This paper is an attempt to further investigate the emergence and evolution of this two-elite system in France over the 1968-2017 period.

Relative to the existing literature, this paper makes several contributions. First, we measure political preferences for very precise and disaggregated political nuances. The specificities of French politics, with a variety of political parties running for elections, allows to give a very detailed picture of local political preferences. While the French political landscape has considerably evolved along the sample period, it is still possible to classify each party along an Extreme Left - Extreme Right axis based on the description of each platform by historians and political scientists¹. Moreover, we use these measures at the level of nearly 3,500 *cantons* and 36,000 *communes*, a much more disaggregated level of analysis than most of the literature on the political and economic legacy of political cleavage in France, which generally relies on the level of 90 *départements*². We also match these electoral results to socio-economic determinants of political preferences, such as age structure, occupation, gender, education and unemployment.

The second significant contribution of this research is to explore the impact of local taxation on aggregated voting behaviors and its interactions with education, income and wealth. Local taxation has not been considered in the literature yet, although it is the one of the few variables that represents the economic dynamic of the *canton* or the *communes*.

¹In this study, we use Julia Cagé's classification of political parties, see Section 2.2.

²In this regard, Pasteau (2018) is our main model of analysis.

Last but not least, local taxation enables us to differentiate between voting behaviors of ‘residential local economies’, defined by Laurent Davezies (2008) as areas with wealthy non-active individuals (such as retirees), and areas with a high economic potential.

More generally, the main innovation of this research is to build systematic long-running series of electoral results and socio-economic inequality measures at a local level, and to focus on disparate voting attitudes at a local level across education, income and local taxation. This decomposition of voting behaviors along socio-economic commensurable inequality variables is useful for comparative studies over long time periods and across countries (Piketty, 2018).

Our main empirical results are the following: first, *cantons* and *communes* in the top deciles in terms of average income (for the 1993-2017 period) tend to significantly vote more for right-wing parties and less for left-wing parties than *cantons* and *communes* in the median decile. More specifically, average taxable income is positively correlated with right-wing vote at the end of the period (2002-2017). It is also negatively correlated with extreme parties. Average taxation during the 2002-2017 period has the same positive and negative impacts as average income, respectively on the right- and left-wing parties, while it does not present any significant correlation with center-wing nor extreme parties. Finally, *cantons* and *communes* in the top deciles in terms of education level (i.e. in terms of population shares of university graduates³) vote more for the left- and less for the right-wing parties than the median decile. They also vote far less for extreme parties than the median decile. These results could be interpreted as follows: first, the emergence of an intellectual elite in France in the 1970s-1980s, who vote more for left-wing parties (Piketty, 2018), is verified in our study. Moreover, the intellectual elite clearly vote against the

³By running the analysis on population shares of baccalaureat graduates, instead of university graduates, we found less significant and consistent results. In fact, since the 1970s-1980s, a large part of the population gets the baccalaureat, which makes this degree not significant enough to illustrate political cleavages in terms of education level.

extreme-parties. In the absence of income as a control variable over the 1968-1988 period, we observe a complete reversal of the education effect, since *cantons* and *communes* in the top deciles in terms of education level now vote more for the right and less for the left-wing parties. This might show that the income effect over this period was predominant, even though multiple political equilibria might have coexisted, depending on individual's type of higher degree or occupation ⁴. Another interpretation would be that highly educated left-oriented voters tended to live less together than wealthy right-oriented voters during this period. Finally, it might also be the case that the reversal of the political cleavage in terms of education *versus* income was not entirely completed at this time period (as shown by Piketty, 2008).

While income and education combined give us great insight on the effect of aggregated individual characteristics, local taxation gives us additional details on the impact of the economic ecosystem of *cantons* and *communes* on voting behaviors. In fact, local taxation is mostly made of corporate tax, which is an indication of the spatial concentration of manufacturing and services. Therefore, *cantons* and *communes* with a strong concentration should favor pro-business attitudes and be liberal-oriented. Our results are consistent with this hypothesis, since areas in the top deciles in terms of average local taxation product vote more for the right- and less for the left-wing parties than the median decile. This interpretation, however, assumes either that the individuals that depend on the firms' welfare are part of the local electorate, or that the presence of a given number of firms at the *cantons* or *communes* level favors the existence of a pro-business electorate.

The identification of this paper relies on comparing deciles of *cantons* and *communes* according to education, income and local taxation, in a cross-sectional framework from 1968 onwards. The first methodological challenge is to classify the plethora of political trends

⁴In fact, teachers, researchers and high-level public agents may tend to vote more for left-wing parties, whereas equally highly-educated individuals, who work in the private sector, may prefer to vote for right-wing candidates.

into comparable categories over time and across countries. We explain this categorization in further details later in the paper. This classification can be difficult since new parties (such as En Marche, Emmanuel Macron’s party) claim themselves as not partisan and gather traditional political aspects from both the right- and the left-wing parties. We should also remain cautious of false causal interpretation for observed trends, since we don’t observe several variables, such as religion, migration or household structure, and since we don’t observe voting behaviors at an individual level. In fact, our analysis poses methodological issues in terms of artificial homogenization of individual voting preferences. Robinson (1950) pointed out the fact that ecological effects cannot be equivalent to individual correlations, in the way that they could cancel individual correlations out. Rather, our analysis focuses on social interactions and spatial influences in terms of voting behaviors. As pointed out by Goodman (1959), in response to Robinson, ecological correlations are of primary interest, since people may socialize in different places and influence each other, which explains a significative spatial difference in terms of voting attitudes. As stressed by Pasteau (2018): “the ecological analysis of electoral results appears to be a valid method as long as there is no straightforward inference of the aggregated relations on the individuals”. Our analysis, which is done at the *cantons* and *communes* levels, is an improvement on these two perspectives, since it gives a more accurate sense of political spatial differentiation and social interactions in voting behaviors than previous works that have been done at the *département* level. Still, for robustness purposes, we compare our results to Piketty’s analysis of post-electoral individual surveys (2018).

The rest of this paper is organized as follows. Section 2 presents historical statistical data on electoral results and time series based on newly collected census data for the 1968-2017 period. Section 3 presents the main specification and empirical results based on historical census data and electoral results at the canton level and focuses on the correlation between education, income and local taxation on voting behaviors during the 1993-2017 period. Section 4 concludes.

2 Data

2.1 Electoral and geographical levels of analysis

In the 20th century French electoral system, several types of elections are sequentially held: municipal, departmental, legislative, senatorial and presidential elections. We chose to focus on the legislative elections for the following reasons, also mentioned by Siegfried in his seminal work (1913):

-municipal elections have only a clear political meaning for big municipalities: for small ones, however, the challenge of the elections is not political *per se*, but rather revolves around personalities and candidates.

-departmental elections are not of prime interest for voters: turnout is often high for this type of elections. The same reason applies for senatorial elections. Moreover, results for these elections are only aggregated at the *département* level and cannot be studied at a smaller local level.

-presidential elections often turn out to be a struggle between two main opponents and thus, the diversity of political opinions is hard to observe. Moreover, alliances between different political parties are often created, making the analysis of each political force more difficult to analyze separately along the traditional left-right political scale.

It follows that legislative elections seem to be the accurate and optimal level of electoral analysis in case of French politics. However, by focusing on legislative elections, one should be aware of two major facts, as shown by Siegfried: “Two conditions should be respected, in order to draw any meaningful interpretation from legislative electoral results: first, one should accurately look at geographical disparities within *circonscriptions*, and secondly, one should carefully study persistent long-term political trends across legislative elections. In fact, interpreting the results of only one election, and extrapolating general

political trends from this single point, would be misleading.” (p. 50). Therefore, we should carefully choose our geographical level of analysis. French metropolitan administrative system is made of six main levels: municipalities (roughly 36 000, depending on the year), *cantons* (around 3000-4000), *circonscriptions* (around 500-600), *départements* (95-100) and *régions* (22). While the literature mainly focuses on the *départements*, we focus on the *cantons*, a far narrower level of analysis, which allow us to increase the number of observations, to better illustrate the local political trends, a fact that Siegfried already mentioned in his seminal work (1913): “*départements* and *circonscriptions* aren’t homogeneous units of analysis for the study of political preferences. *cantons*, however, seem to be the most natural and easily observable political units: they are expanded enough to avoid excessive details and small enough to comprise homogeneous political trends” (p.51). Sometimes, the use of municipality data is also useful, in case of infra-cantonal political divisions: “However it happens sometimes that the canton comprises different political trends. In this case, one needs to study one’s political object at the municipality level” (p. 52). Individual data are of course the most accurate level of analysis. However, although post-electoral survey data, used by Mayer (2004) or Piketty (2008), have obvious advantages, such as gathering individual data on electoral behavior, socio-demographic and economic characteristics, they also have major flaws: their sample size is limited, and they don’t exist before the 20th century. Therefore, in the absence of long-term series of individual electoral preferences and census data, a second-optimal level of analysis is the use of legislative electoral results, census and fiscal data, either at the municipality or at the *canton* level. Moreover, analyzing both geographical scopes allows to detect aggregation effects, such as endogeneous choices of localization for households. In fact, we might observe different results between both levels, as it is more likely that we observe less heterogeneity in terms of socio-economic and socio-demographic characteristics between cantons than between municipalities (since population with the same characteristics often

live in the same cross-municipalities surroundings). For all these reasons, this paper deals both with the municipality and the *canton* level.

2.2 Electoral results and classification of political parties

Legislative elections. In this paper, we focus on the 1968, 1973, 1978, 1981, 1986, 1988, 1993, 1997, 2002, 2007, 2012 and 2017 legislative elections. Legislative elections take place every 5 years in France. Since the French president can dissolve the National Assembly, more frequent elections can occur (which explains why our election time periods fluctuate). Data are available online at all levels from 1993 onwards. Data from 1968 to 1988 are only available at the *département*, *circonscription* and *cantons* levels ⁵.

Nowadays, the French National Assembly has 577 seats - one for each constituency (*circonscription*) ⁶. In order to obtain a majority of votes, a political party must win a total of 289 seats in any *circonscription* in a two-round process: if a candidate wins 50% of the votes and a minimum of 25% of the votes at the end of the first round, there is no second round. However, since most *circonscriptions* have several candidates, this case is rare, and the two candidates with the most votes during the first round move to a second ballot. More than two candidates can move to the second round of elections, since any candidate with at least 12.5 percent of all registered voters in any *circonscription* is eligible for the second ballot. The candidate who obtains most votes win.

Classification of political parties. While legislative electoral results at a departmental level are relatively easy to find - the Centre de données socio-politiques (CDSPP) has digitalized harmonized electoral data for the Fifth Republic (1958-2012)-, this is not the case of *cantons*'s level data. We gathered cantonal electoral data from the Ministry of

⁵For this time period, we use the data from the Centre de Données Socio-politiques, as well as Nicolas Sauger's election results by *cantons*.

⁶The number of seats varies over the years

the Interior and digitalized them. We focus our analysis only on the results of the first round of the legislative elections. In fact, results of the second rounds often conceal the diversity of political opinions since only the two most-voted candidates can take part. Moreover, some political parties, such as regionalist or some specific federations, have no clear positioning on the left-right political scale. Therefore, we don't take them into account. We rather focus on the extreme-right, center right, center left and extreme left parties, which we classified as follows ⁷:

Year	Extreme-left	Centre-left	Centre-right	Extreme-right	Diverse
1968	PC, app. au PC, PSU, ext. gauche	FGDS, Radicaux-socialistes	UDR, RI, RI/UDR, PDM, div. gaullistes, Radicaux de droite, Modérés	Alliance républicaine, div. ext. droite	Mouv. pour la réf., divers, Tech. et dém., régionalistes

On top of these four categories, we analyze the right and left categories, that respectively gather the center- and extreme-right and the center- and extreme-left votes. Shares of votes for each of these political trends are described in Table 1 below. Furthermore, at this stage of the analysis, we restrict our study to plain vote shares and exclude turnout as a potential dependent variable, although it can be considered as a major determinant of the vote shares' magnitude of the different political parties (see Braconnier and Dorgan, 2007, for a sociological analysis of turnout in Paris area).

⁷The following table represents the classification of the main political trends only. However, the raw election results contain a myriad of political parties that have been classified by Julia Cagé (see References). This study uses Julia Cagé's classification.

2.3 Census data, income and local taxation

Census data. Census data with socio-demographic variables, such as occupation, education, age and gender, are available online for the 1968-2015 period, at the municipal level. We make use of a table of equivalence between municipalities and *cantons* to aggregate municipal census data at the level of our unit of analysis ⁸. For each election year, we compute a linear extrapolation of every census variable by averaging the census data of the previous and following elections, by weighting more the census results closer to the election year.

Local taxation and income distribution. . The local taxation and the income structure at the municipality level are only available from 1993 (for income) and 2002 (for local taxation) onwards. We collected local taxation data at the municipality level for the 2002-2017 period that are made available by the Tax Directorate of the Ministry of Economy and Finance. French local taxation system did not vary much across time during the 1968-2017 period, although some tax did change names. They are four main types: housing tax, property tax imposed on constructed and non-constructed property and corporate tax. As for income distribution, the average net income is only available at the municipality level for 1993 and 1997. We use the average taxable income, which is available from 2002 to 2017, as a proxy for the average net income for the subsequent years of the analysis. To get a general perspective on the effect of socio-economic inequality on voting attitudes, we first compute the average net and taxable income and tax level per adult as the ratio of total net or taxable income/ total local tax revenue over the number of adults aged more than 20 years old, to make levels comparable over time across *cantons* and *communes* (see Section 3).

⁸This table of equivalence has been created by Frédéric Salmon.

Tables 1 and 2 show descriptive statistics for our main socio-demographic and socio-economic variables each year, both at the *cantons* and *communes* level. Sources for census, average income and tax ratio are described in Appendix A1-A3.

As expected, the share of elderly on the active population increases over the period (from around 20% to 28% per cent), as well as the share of the population who holds a university degree (from 2% to 23%), due to the so-called democratization of education in the 1960s. Interestingly is also the participation, which shrinks from 80% to 50% at the end of the period. This might induce that the results that we get at the end of the period should be carefully interpreted, as they show the impact of socio-economic and socio-demographic characteristics on the voting behaviors of a restricted sample of the population.

Another notable fact is the number of *cantons*, which is reduced by almost half between 2012 and 2017. This follows the law that was passed on the 17 May 2013, which proceeds to a rezoning of *cantons* so that parity in departmental elections is imposed and that voters can chose two elected representatives of both sexes.

In order to provide some context for the interpretation of the main results, other descriptive tables are provided in Appendix A4. They represent the number of units (either municipalities or *textitcantons*) for each decile of the share of the population in terms of university graduates, tax ratio and income level, as well as for the top 5% and 1%.

2.4 *Cantons*' boundaries

One major issue of our analysis is the change in *cantons*' boundaries across time. *Cantons* have changed a lot since 1968: around 400 of them were divided and 200 of them were reunited, while most of the remaining *cantons*' administrative boundaries have experienced expansion or size reduction (Gaudillère, 1995). The challenge of our analysis is to consider comparable *cantons* and try to exactly match *cantons* over the years, in order to rigorously analyze evolution in voting behaviors. To do so, we rely on Salmon's *cantons* maps and table of equivalence for the 1968-2012 period (Salmon, 2018), and on the Ministry of Interior's table between 2012 and 2017, to attribute matching identifiers for each canton over the whole period. Although Gaudillère (1995) shows that municipalities's boundaries have experienced a few changes, we assume that they remain substantially the same for simplification purposes. We then use the Code géographique officiel (INSEE, 2012) to aggregate municipalities' income distribution, local taxation level, and socio-demographic variables to the *canton* level.

3 Estimation method and preliminary results

3.1 Specification

Following Pasteau (2018), at the *canton* and *commune* level, we first implement a simple OLS in order to look at basic correlation patterns in cross-section for each year of study by clustering standard errors at the *département* level (each *département* contains several *cantons*):

$$y_{it} = \gamma I_{it} + \beta X_{it} + \epsilon_{it}(1)$$

Where i is the canton index, t the year of study, Y the vote share considered (either extreme-right, center-right, center-left, extreme-left), I is our variable of interest (either average net or taxable income, local tax ratio, or education) and X a set of socio-demographic and economic variables, such as gender, age, occupation, rurality and education (when it is not used as a variable of interest). The main focus of this study is the analysis of cross-sectional correlation, and not causality, between our dependent variables (voting shares) and our variables of interest. In fact, we aim at extending Piketty's descriptive findings on France at a local level (Piketty, 2018), regarding education and income, such that we are rather focusing on historical changes in voting behaviors and political cleavages than in causal relations between variables.⁹

Voting shares are standardized by using the following computation:

$$y_{it} = \frac{sC_{it} - s\bar{C}_t}{\sigma_{sC_t}}$$

⁹Other variables, such as the level of religious observance for instance, are obviously missing, leading to an endogeneity issue that does not allow for causal interpretation. We omit religion because of the absence of consistent and comparable data across time at the *cantons* and *communes* level. In any ways, endogeneity might also occur through unobservables that we are not able to control for in this study.

Where sC_{it} is the voting share for candidate C in the canton i in the year t, $s\bar{C}_t$ is the voting share for the candidate C at the national level in the year t, and σ_{sC_t} is the standard deviation of the vote gained by C in the year t.

Finally, variables of interest and control variables are fractioned in deciles, weighted by the population of registered voters, and all results must be interpreted with respect to the 50-60 decile.

3.2 Results

First, we analyze the cross-sectional correlations between education and voting behaviors for the 1968-2017 period. We haven't disaggregated data on income at the canton level for the 1968-1988 period yet, so for this period, it will be hard to disentangle the education effect from the income and the wealth effects. Secondly, we focus on the relationship between average local taxes and income per adult and voting behaviors from 1993 onwards. It is worth noticing that we observe the same trends (in terms of sign and magnitude of the correlations) both at the municipality and at the *cantons* level. Our hypothesis that we would observe endogenous localization effects of the households do not seem to hold, at least at the *cantons* level. Therefore, the following results present the range of magnitude at both levels and for both the top 5 and 1 of the distribution, either in terms of education, income or local taxation (see tables in Appendix for further details).

3.2.1 Focus on the educational effect (1968-2017)

The top deciles in terms of share of university graduates seem to be significantly and positively correlated with left-wing voting behaviors and negatively correlated with right-wing

voting behaviors (if we consider by left-wing -respectively right-wing - votes the votes for the extreme-left, the center-left and the left -respectively the extreme-right, the center-right and the right- parties). The magnitude of these correlations goes from 0.6 to 1.4 standard deviations of vote for left-wing parties and from 0.3 to 1.4 standard deviations of vote for right-wing parties over the 1993-2017 period. This variable does not show any significant and consistent correlation with the center-left or right parties but displays a significant negative correlation with extreme-wing parties, which goes from 0.5 to 1.4 standard deviation, depending on the year of analysis.

The following present these results for 2012 at the municipality level:

Note: Standardised share of vote for the left in the first round of French legislative elections. The effect on the vote is expressed in standard-deviation of the vote. The share of university graduates is the share of individuals aged more than 20 with a university diploma in the municipality. Income is the average taxable income per adult in the municipality. Population density is the ratio of the total number of municipal residents over the municipal surface area. Control variables:., share of women, share of the population aged 20 to 35, share of the population aged 65+, share of workers, share employed in the industry, share employed in agriculture, unemployment rate, population density. Standard errors are clustered at the département level.

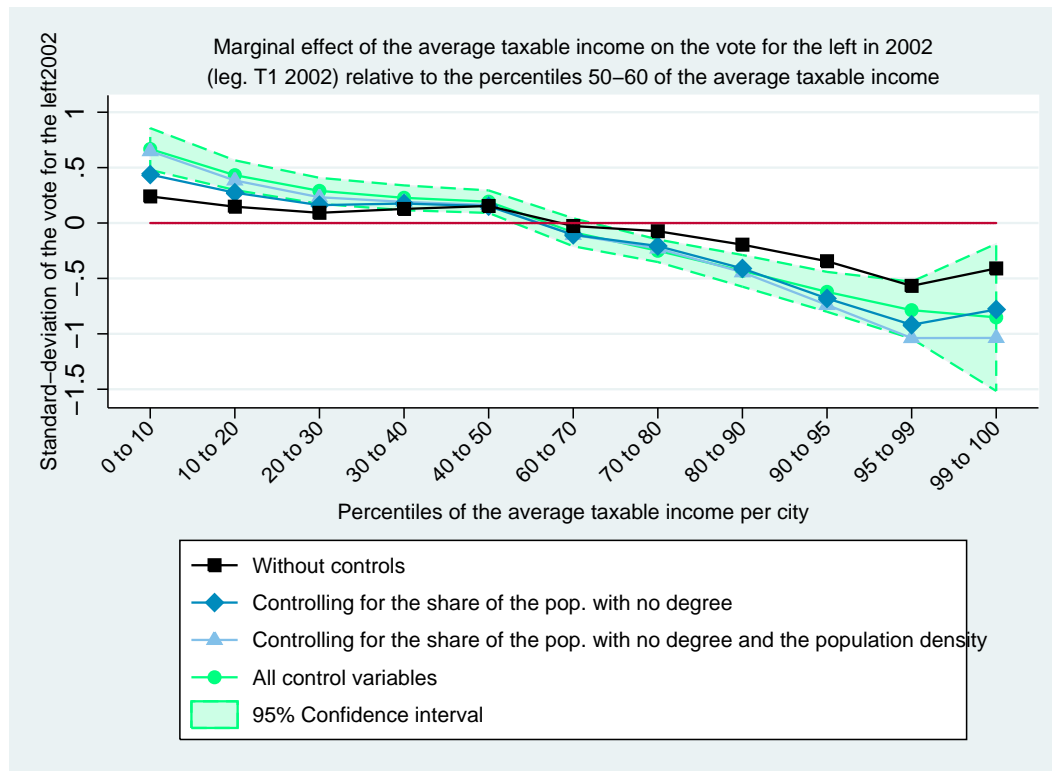

It is also worth noticing that for the 1968-1988 period, while we do not control for income because of the lack of accessible data, the correlation between education and left/ right voting behaviors goes in the opposite direction than the correlation from 1993 onwards (once we control for income), i.e. the top deciles in terms of share of university graduates seem to be significantly and positively correlated with right-wing voting behaviors and negatively correlated with left-wing behaviors, as show in this example at the municipality level for 1993:

3.2.2 Focus on the income (1993-2017) and the local taxation effect (2002-2017)

The net and taxable average income is also significantly and negatively correlated with extreme-wing voting behaviors, with a magnitude of 0.5 to 0.9 standard deviations for the extreme-left and 0.3 to 0.8 standard deviations for the extreme-right. It is worth noticing that the impact of income on the extreme-right vote is less negatively significant at the municipality level (only negative, 0.4st. deviation, at the end of the period) than the impact on the extreme-left vote (which is consistently and significantly negative over the 1993-2017 period, from 0.3 to 0.8 st. deviations). In contrast to education, net and taxable income is negatively correlated with left-wing parties (0.3 to to 1.8 st. deviations) and positively correlated with right-wing parties (0.3 to 1.7 st. deviations).

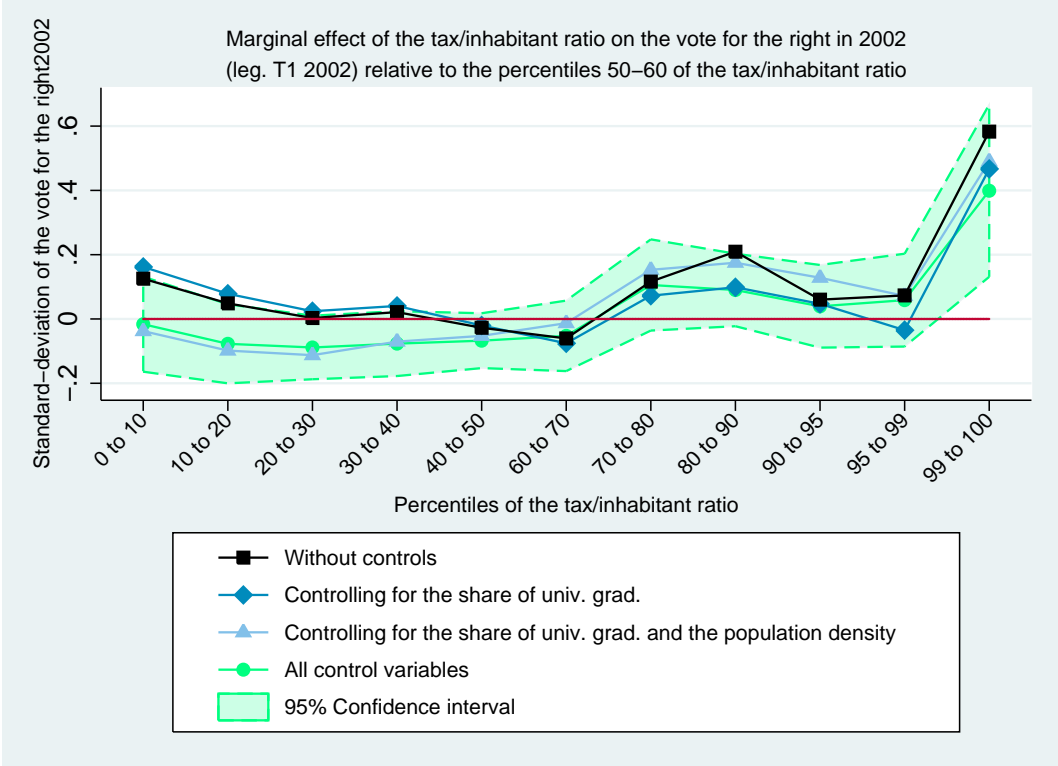

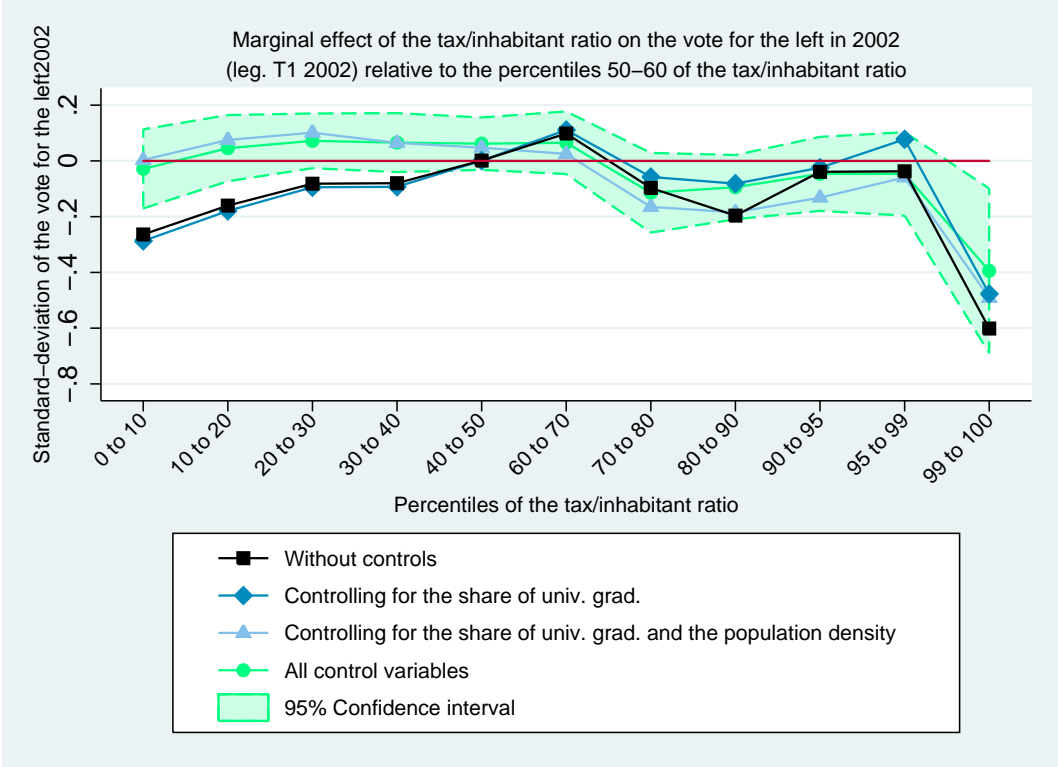

The following present these results for 2002 at the municipality level:

Finally, the impact of the local tax product ratio on voting behaviors goes in the same direction as the impact of net and taxable average income, since it is significantly and

positively correlated with right-wing parties (0.3 to 0.8 st. deviations) and negatively correlated with left-wing parties (0.3 to 0.8 standard deviations).

The following present these results for 2002 at the municipality level:

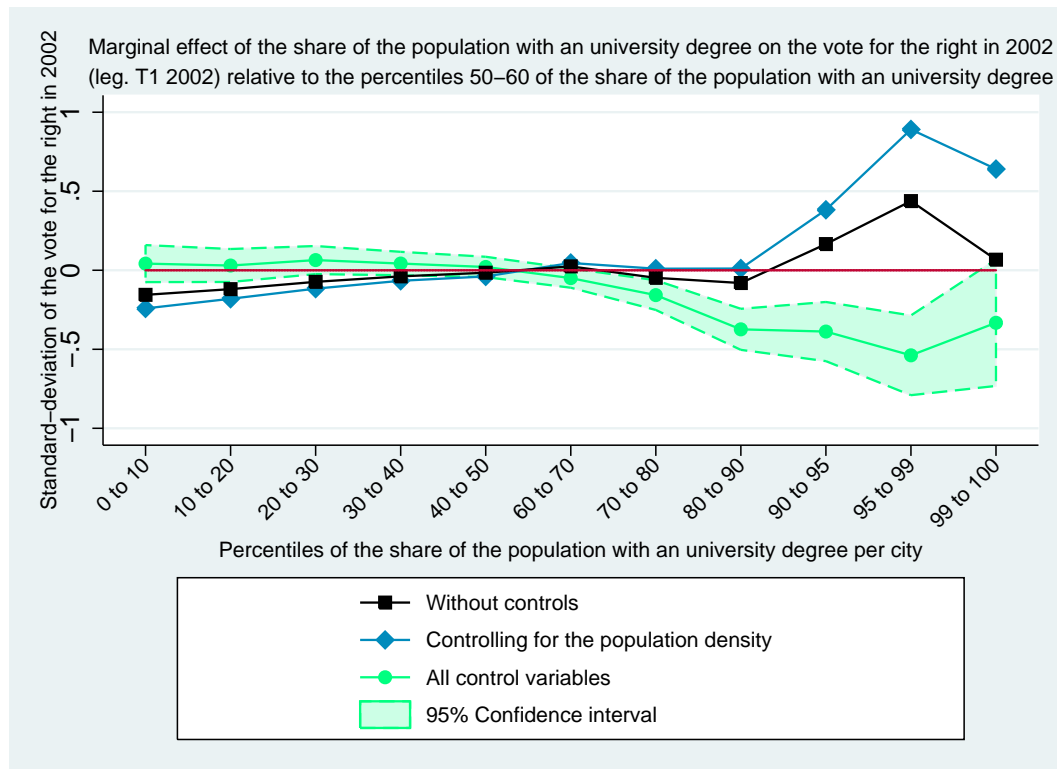

These results corroborate previous findings in the literature. First, the reversal of the political cleavage in terms of education – left-oriented intellectual elite *-versus* income - right-oriented business elite - was not entirely completed in the beginning of the period (Piketty, 2008). In fact, in his paper, Piketty shows that, in the 1950s-1960s, the more educated voters were the ones who voted for the right-wing parties, while, at the end of 2010s, the higher the education level, the higher the left-vote. The reversal in the education gradient would have taken place gradually, a fact that we also observe in our results. Secondly, we also corroborate Pasteau’s results (2018), which report a positive and significant correlation between average income per adult and vote for the right, a negative correlation between average income per adult and vote for the left, and a positive correlation between education and the extreme-right, at the municipality level. We expand these results and show a positive impact of education on voting behaviors for the left and a negative one for the right. Moreover, we show that the local taxation effect goes in the same direction as the income, which makes this variable less informative than expected for explaining voting behaviors in a spatial perspective.

3.2.3 Robustness check

These results are robust to the inclusion of a wide range of control variables, such as the population density, the share of women, the unemployment rate, the share of workers and employees, the share of the population between 0 and 20 years old and more than 65 years old. As an additional robustness check, we also include the share of votes (from left to right) in 1968 as a control variable in all regressions from 1973 onwards, in order to control for past political trends and partly take into account omitted variables, which might have influenced past election results. The previous results for education and income hold.

The following present these results for 2002 at the municipality level:

Note: All previous control variables are included. The share of votes for the right in 1968 is added as a control variable. Standard errors are clustered at the département level.

Note: All previous control variables are included. The share of votes for the left in 1968 is added as a control variable. Standard errors are clustered at the département level.

4 Conclusion

This study gives some insight on the correlation between education, income, local taxation and voting patterns both at the canton and municipality levels, over the 1968-2017 period. We build long-running series of socio-demographic and socio-economic variables, as well as electoral results on the whole period, in order to analyze the historical evolutions of the political cleavages in France. We corroborate both Piketty's and Pasteau's findings, by showing that *cantons* and *communes* in the top income (for the 1993-2017 period) and local tax ratio deciles (for the 2002-2017 period) tend to significantly vote more for right-wing parties than those in the median decile, and less for left-wing parties. The fact that education has an opposite impact before and after 1988 either shows that the voting habits of the higher educated part of the population changed over time, or that the income effect, which is not taken into account for the 1968-1988 period, is predominant.

However, this study is mostly descriptive and does not show causal relations (even though our results are robust to multiple specifications, including various control variables and past voting trends). Further avenue for research should deal with the omitted variable issue, by expanding our data collection to religious observance or migration, for instance. Moreover, one should try to collect consistent data on wealth over the whole period of analysis in order to disentangle the effect of wealth and income on voting patterns. Finally, expanding the data collection back in time would be a formidable challenge, in order to trace back the evolution of political cleavages in France before the 1950s-1960s.

A Appendix

A.1 Census

The INSEE has digitalized census series at the municipality level for the 1968-2015 period, which contain the following data (among others):

-occupation categories: number of working individuals classified as workers, entrepreneurs-merchants, employees, executives, farmers and intermediary professions.

-(un)employment: number of active versus unemployed individuals per municipality.

-age categories: number of individuals per age category (from 0 to 95 years old, 5-year categories, and one last category for 95+ years old individuals).

-gender: number of men and women per municipality.

-education level: number of individuals per municipalities who do not hold any degree, who hold a CAP/BEP (professional degree), a baccalaureat degree, and an university degree.

All variables are available for the following years: 1968, 1975, 1982, 1990, 1999, 2010 and 2015. These series are available online.

A.2 Income and tax data

Data on the average net and taxable income at the municipality level are made available on request by the Quetelet Progedo Diffusion project. Originally, data were gathered from DGFIP and INSEE.

The average net income is only available at the municipality level for 1993 and 1997. We use the average taxable income as a proxy for the average net income for the subsequent years of the analysis (2002 to 2017). The average taxable income is defined as the cumulated amount of taxable income of all fiscal units divided by the number of fiscal units within a city. The net income is defined as the cumulated net income of all fiscal units divided by the number of fiscal units within a municipality. Both variables are averaged at the *canton* level, when needed.

Data on local taxation product are available online on the DGFIP website, from 2002 onwards. Our local taxation product variable is defined as the sum of the main categories of local taxes (real estate tax, land tax, professional tax), divided by the number of individuals within each municipality, who are 20+ years old. This variable is averaged at the *canton* level, when needed.

A.3 *Cantons* maps and table of equivalence between *communes* and *cantons* for the 1968-2017 period

In his book *Atlas historique des circonscriptions électorales françaises* (1995), Bernard Gaudillère describes the methodology that he used to draw the evolution of all administrative units of France (from the municipality to the *département*) across history. The

following extract (in French) gives some insight on his sources regarding the geographical changes of the *cantons* since the 19th century:

‘Une cartographie aussi rigoureuse eut nécessité deux dépouillements exhaustifs : soit celui des procès-verbaux d’élections [...], soit subsidiairement celui des Bulletins des Lois et Journaux Officiels, indiquant les changements de rattachement cantonal des communes. Un tel travail, mené dans quatre-vingt-dix départements, excédait de très loin les capacités d’un chercheur isolé.

On a donc, dans la plupart des cas, donné aux cantons leurs limites actuelles, mais en y apportant de nombreuses corrections, à la lumière des diverses sources :

-la “Carte Cantonale de la France”, dite “carte Donnet”, dressée en 1817 et révisée en 1884.

-les volumes départementaux de deux ouvrages : le Dictionnaire Topographique de la France (34 volumes parus) et Paroisses et Communes de France (éditions CNRS ; 21 volumes départementaux parus).

-les arrêtés consulaires de 1801-1802, qui ont tracé la première division cantonale. Ils sont notamment indispensables pour reconstituer les cantons périphériques des villes, qui ont aujourd’hui disparu.

-les lois et décrets créant de nouveaux cantons après 1801-1802. ‘

Frédéric Salmon completed Gaudillère’s substantial work and created a table of equivalence between *cantons* over time, as well as *cantons*’ maps, based on the following additional sources:

-he used INSEE and IGN maps from the 1960s, that he corrected based on the collect and the revision of some publications of the Bulletins des Lois and Journaux officiels.

-he created maps of cantons after 1966 by using the “Index Atlas de France” (Oberthur,

1976).

A.4 Descriptive tables

The following tables represent the number of units (either municipalities or *cantons*) for each decile of the share of the population in terms of university graduates, tax ratio and income level, as well as for the top 5% and 1%.

Table 3: Descriptive statistics of the share of higher degree's deciles for the 1968-1997 period *canton* level (reference for codification of the *cantons*: Salmon's table of equivalence, see Appendix A.3.)

Note: this table provides descriptive statistics (the average share of adults with a higher degree and the average number of registered voters) for higher education's deciles (weighted by the number of registered voters) for the first round of each legislative election between 1968 and 2017 in Metropolitan France.

Table 5: Descriptive statistics of the tax/inhabitant ratio's deciles for the 20022017 period - *canton* level (reference for codification of the *cantons*: Salmon's table of equivalence, see Appendix A.3.)

Note: this table provides descriptive statistics (the average tax/inhabitant ratio and the average number of registered voters) for tax/inhabitant ratio's deciles (weighted by the number of registered voters) for the first round of each legislative election between 2002 and 2017 in Metropolitan France.

Table 6: Descriptive statistics of the tax/inhabitant ratio's deciles for the 20022017 period - municipality level (reference for codification: 2012)

	(2002)			(2007)			(2012)			(2017)																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																																						
	ratio of total local taxes over the active pop.	registered_voters	ratio of total local taxes over the active pop.	ratio of total local taxes over the active pop.	registered_voters	ratio of total local taxes over the active pop.	ratio of total local taxes over the active pop.	registered_voters	ratio of total local taxes over the active pop.	registered_voters	ratio of total local taxes over the active pop.	registered_voters

Note: this table provides descriptive statistics (the average tax/inhabitant ratio and the average number of registered voters) for tax/inhabitant ratio's deciles (weighted by the number of registered voters) for the first round of each legislative election between 2002 and 2017 in Metropolitan France.

Table 7: Descriptive statistics of the average net taxable income's deciles for the 19932017 period - *canton* level (reference for codification of the *cantons*: Salmon's table of equivalence, see Appendix A.3.)

	(1993)			(1997)			(2002)			(2007)			(2012)			(2017)		
	Average net income	registered_voters	Average net income	registered_voters	Average net income	registered_voters	Average taxable income	registered_voters	Average taxable income	registered_voters	Average taxable income	registered_voters	Average taxable income	registered_voters	Average taxable income	registered_voters
