# Capital Gains and Income: Real Changes in the Value of Capital in the United States, 1946-77 

Robert Eisner

Personal income may be defined as the algebraic sum of (1) the market value of rights exercised in consumption and (2) the change in the value of the store of property rights between the beginning and the end of the period in question.

Henry Simons
Income is the money value of the net accretion to one's economic power between two points of time.

R. M. Haig

Income No. 1 is thus the maximum amount which can be spent during a period if there is to be an expectation of maintaining intact the capital value of prospective receipts.

Income No. 1 ex post equals the value of the individual's consumption plus the increment in the money value of his prospect which has accrued during the week; it equals Consumption plus Capital accumulation.

We are thus forced back on the central criterion, that a person's income is what he can consume during the week and still expect to be as well off at the end of the week as he was at the beginning.
J. R. Hicks

### 5.1 Sources and Nature of Capital Gains

The late Howard Hughes and the late J. Paul Getty, the Rockefeller family, and the rich the world over did not gain their wealth by the flow of saving out of conventionally measured income. Rather, they

[^0]discovered or acquired title to resources that grew enormously in value, or they bought and sold, exchanged and held real assets, securities, and businesses that appreciated.

The wealth of nations has waxed and waned with the acquisition and development of land and its resources and with changes in world demand and supply of the products and services in international commerce. Oil-producing countries have become rich with the discovery of petroleum and increases in its price. Cuba's wealth has declined and grown as much with changes in the price of sugar as with investment by citizens or foreigners. Fortunes of all of the world's raw-materialproducing nations have depended mightily on their terms of trade.

Within the United States, in the South and in the West, in particular areas within all regions, in suburbia and farmlands, we have had great increases in wealth, enjoyed by individuals and communities alike, far beyond officially recorded saving. It is clear that the distributions of economic power, of consumption, and of properly measured income have been vastly affected by appreciations in the value of property commonly referred to as capital gains.

National income and product accounts of the United States and elsewhere presume to measure the total of consumption and investmentthat is, the current production of goods and services received by households and the accumulation of stocks of goods by producers. Aside from the role of the rest of the world and of government, this total is widely rationalized as income in the sense-to paraphrase Hicks-of what can be consumed during the period of measurement while still leaving society as well off at the end of the period as it was at the beginning. For. at least with perfect elasticity of substitution between capital goods and consumer goods over the relevant range, our measure of net income would then be the amount by which the production and consumption of consumer goods and services could be increased while reducing gross investment to the amount of depreciation or net investment to zero.

[^1]The essential difficulty in relating conventional data of consumption and investment to income in the Haig-Simon and Hicksian senses is that investment as currently measured may be poorly related to capital accumulation. Gross investment in conventional accounts is taken as the original cost or supply price of acquisitions by business of capital goods and additional inventories. There are a number of reasons why this measure does not correspond to capital accumulation in the economy.

First, of course, capital goods-that is, goods contributing to future production-are acquired in both government and household sectors. Not only do these contribute to production in those sectors but-particularly with government-because of externalities or transfers at less than cost, they may contribute to future production in the business sector as well. The values of future services or output of a store, warehouse, or factory may be increased by government construction of a highway. These outputs and their values may also be increased by more free or improved public education of labor.

Second, the business sector itself may increase the value of expected future services and output by investing in research and development, training, and other forms of intangible capital not usually counted as part of investment.

Third, because of conditions of monopoly or monopsony, or monopolistic or monopsonistic competition, along with considerations of risk, firms may not acquire capital to the point where the present value of expected future returns from the last unit acquired equals its supply price. The value of capital acquisitions to firms may be more at the time of acquisition than their supply price.

Fourth, after acquisition the value of capital assets may change because of changes in expected prices of the goods and services to be produced or of associated factors of production whose services are to be purchased.

Fifth, after capital goods are acquired, their values may change because of changes in market rates of interest or rates of discount to be applied to expected future returns.

The first three of the considerations above may be met with a comprehensive treatment of capital investment. Such treatments are to be found in recent work by John Kendrick (1976) and in work I have in process (see Eisner 1978 for a preliminary report).

Even with inclusion of all forms of capital in our measurement, capital gains and losses owing to changes in expected prices and interest rates will still need accounting. As far as price changes go, one cannot assume they represent nothing "real." Net income should include consumption plus the money value of real capital accumulation. This means that only the money value of capital gains in excess of those necessary to keep the real value of capital intact should be included
in income. There is no reason, however, to expect all prices to move in proportion or hence to expect that, for any individual, firm, or sector, capital gains so defined net of general inflation should be zero. In an open economy, as my introductory remarks have suggested, changes in international relative prices may cause capital gains and losses in individual countries.

Capital gains or losses from changes in the rate of interest or rate of discount of expected future returns may not at first glance seem to fall into the category of our usage of income. Suppose, for example, we are dealing with a perpetual annuity. A fall in the rate of discount would increase the present value of this annuity but would not enable us to consume any more currently without reducing the amount permanently available in the future.

This difficulty disappears, however, when we recognize that the individual's utility function, or the social welfare function implicit in evaluation of society's income, may not call for consumption in perpetuity. "Keeping wealth intact" must involve some at least implicit intertemporal valuations. A fall in the rate of interest may well make it possible for individuals or societies to consume more now while still being indifferent between the new vector of incomes or consumptions available in the future, after the fall in the rate of interest and increased current consumption, and the vector that had been available on the basis of the previous rate of interest, value of capital, and consumption. As individuals or as societies we may have wealth that is the present value of an expected future stream of income that does not correspond to our preferred and planned future consumption. A lowering in the rate of interest may increase the value of that wealth and enable us as a consequence to plan a path of consumption that dominates the previous path.

This is perhaps clearest in the case of an individual contemplating retirement who finds that a change in the rate of discount for his expected future incomes raises his wealth more than it does his desired or planned estate. He is then able to consume more now and still have at least as good a planned consumption path (and planned estate) as before. It may be argued that he will require a larger planned estate if his ultimate motivation is to provide a fixed consumption path for his heirs. But this again would require an assumption, not necessarily warranted, that a future consumption path he preferred for his heirs correspond to the anticipated income stream.

Similarly, a nation may anticipate from its resources a stream of future income that does not correspond to its preferred consumption path. A fall in the rate of interest, which may relate to investment in or from the rest of the world and reflect the differing rates of discount across nations, may raise the capital value of this nation's resources. By sell-
ing off some of its increased capital value internationally, the nation as a whole may then consume more now and still be at least as well off as before with regard to future consumption. Here again, therefore, we have a change in the rate of discount that, with no alteration in expected future incomes, involves a capital gain usefully viewed as a component of current income.

Capital gains may also accrue, both for the individual and for the nation, with changes in expected future incomes resulting from the discovery of new resources or new techniques of production. A major source of wealth in the United States has of course been the development of new land, not conventionally included in investment. Along with the land have come literally hundreds of billions of dollars of resources in coal, petroleum, and other minerals. Inventions and innovations, from the cotton gin to the steamboat, the railroad, the telephone, the automobile, and the jet plane have made much of this land and its resources more accessible and more valuable. Such increased values of assets may indeed stem from externalities of investment elsewhere, but they are none the less real and should be taken into account in our measures of capital accumulation and hence of income.

Much of the issue in the relation between capital gains and income is sometimes viewed as a matter of the timing of income (see McElroy 1976). If new resources are discovered, should we count the present capital gain as part of current income, or should we note the increase in income only in the future as revenues are received from the additionally discovered or developed resources? It is sometimes argued that inclusion of capital gains (and subtraction of losses) in measuring current income will make current income all the more unstable and less relevant as a measure of permanent income and welfare. To the extent that our concern is for permanent income, this point is telling. But then we should have to completely revise our conventional accounts, which deal generally with current, measured incomes, regardless of their variance over time. We do not smooth out our national income or gross national product to reflect major fluctuations in corporate and noncorporate profits or in wage income owing to movement in and out of employment and the labor force. It appears best for many purposes to include capital gains in a comprehensive measure of current income and add a comprehensive measure of permanent income that would treat all volatile accretions of economic power equally.

We shall generally make no distinction between realized and unrealized capital gains. Economic power grows as capital gains accrue. Economic power diminishes as capital losses occur. Individuals usually have the option of realizing capital gains, although with some transaction costs and tax penalties. If they choose not to realize their gains, then presumably they feel themselves better off without realization. The
gains remain available as a base for further accumulation or even for current consumption without "realization," either by permitting reduction of other saving or accumulation or by offering additional opportunities to borrow with the appreciated capital as collateral.

In principle, transaction costs and tax costs of potential realizations should be recognized in measuring accrued capital gains to individuals and firms, but these frequently are minor. With regard to taxes in the United States, half of realized capital gains have been excluded from taxable personal income. The new tax law of November 1978 raises the exclusion to $60 \%$. (There are further, now expanded exclusions for gains realized on the sale of homes.) But taxable realized capital gains are only the appreciation of those assets actually sold. Thus, for example, if one wishes to realize the gain on $\$ 100,000$ of assets that have grown in value by $10 \%$, to $\$ 110,000$, one may sell off $\$ 10,000$ of the appreciated assets. The capital gains tax applies then only to the gain on the $\$ 10,000$ of assets that have been sold, or $\$ 909$. Of this, half would have been excluded from taxable income, so that even at the maximum income tax rate of $70 \%$ the total tax would be less than $\$ 320$ on realization of a gain of $\$ 10,000$, or little more than $3 \%$. With the new $60 \%$ exclusion, the tax is reduced to less than $\$ 255$, or about $2.5 \%$ of the capital gain.

It is of course also true that many individuals and firms may enjoy their capital gains without ever planning to realize them for tax purposes. In the United States one can still avoid capital gains taxation in gifts or bequests. As indicated above, one can accept accrued capital gains as part of saving and thus reduce other saving and increase consumption without "realizing" the capital gains. And one can borrow against assets for consumption or other purposes. Taking into account the lack of taxation in gifts and bequests and the time at which accrued capital gains are eventually realized, Martin Bailey (1969) estimated the effective rate of taxation of capital gains at 8 or $9 \%$.

For nations as well, realization may in essence take place with accrual. Increased wealth affects consumption and international investment flows, whether appreciated assets are actually sold or are used as a base for borrowing or other investment.

Establishing the value of capital for purposes of measuring capital gains and losses involves a number of fundamental problems. In principle, with certainty, perfect knowledge, and perfect markets, and without externalities, the value of capital to individuals, firms, and the economy will equal the present discounted value of its future returns. In fact, we never know future returns, although we can make various efforts to infer expectations of those returns, either our own expectations or those held by firms or investors. Where there have been market transactions
we may accept the values established in the markets for the capital directly involved in the transactions.

Only a small portion of capital assets are actually sold in any short period, however. How are we to infer the value of those assets that are not sold? An initially appealing approach would have us group assets as far as possible into homogeneous categories and infer the value of stocks not traded from prices established in the relatively minor flow of actual transactions.

The extent of the difficulties in this approach may be recognized even in the relatively well-suited case of listed securities on organized exchanges. Can we, for example, correctly infer the end-of-year market value of stocks listed on the New York Stock Exchange from the closing prices on 31 December? Could all the shares of General Motors have been sold on that day or even during any other day or reasonably bounded set of days at the prices paid for those shares actually sold?

One evidence that many firms and investors do not view prices of current transactions as reliable measures of the value per share is both the recurrence and the fear of takeovers of companies by tender offers. A stock may be selling at about $\$ 11$ per share in terms of current transaction flows when an offer may be made to buy enough shares of a company to gain control of it at a price of $\$ 21$ per share. Cases of this sort are too common to allow confidence that flow transactions prices, particularly with their wide gyrations over relatively short periods of time, are reliable measures of capital value.

Indeed, these considerations do raise further questions with regard to our decision to take "accrued" capital gains at face value. If the amount of accruals is estimated from marginal transactions, are there potential realizations for the entire stocks of capital anywhere near equal to those suggested by these marginal prices?

I raise these questions to bring the issues into the open. Nevertheless, in much of our empirical work we do utilize market valuations established on the basis of marginal or flow transactions. Indeed, we and others proceed in essentially similar fashion by using supply prices for the current flow of real goods in estimating market values of corresponding stocks of existing real capital. Such valuations involve essentially application of the "replacement cost" measure that has been adopted by the Bureau of Economic Analysis in estimates of residential and nonresidential capital stocks. These estimates will form an essential part of our analysis. We hence implicitly accept such a valuation for want of a better, available substitute.

Use of replacement cost accounting in the gross valuation of capital stocks leaves a major issue in specifying the depreciation or capital consumption allowances necessary to arrive at net values of capital. The
replacement cost is of course at best the value of a new asset. What is the value of existing assets of various ages? Capital gains must equal changes in the value of capital minus net investment. But to calculate net investment we must know not only current gross investment but also the depreciation of existing capital.

For given successive values of net capital stock, the higher the estimate of depreciation and hence the lower the estimate of net investment, the higher will be the estimate of capital gains. Since depreciation and capital gains are properly the two components of total revaluations of existing assets, if the revaluations are known, the estimate of the one depends critically upon the estimate of the other.

Where net capital value is estimated as a cumulative sum of past net investment, the more rapid the rate of depreciation, real or assumed, the lower the value of reported net capital stocks. Also, given the general growth in the rate of gross capital expenditures, the more rapid the rate of depreciation the higher will be annual depreciation charges and the lower will be net investment. Finally, if revaluations are then calculated as the difference between net stock at the end of a period and the sum of the net stock at the end of the previous period plus the intervening net investment, the more rapid the assumed rate of depreciation the lower will be the calculated revaluation. In the limiting steadystate case where all new investment is fully depreciated in the period it is made, there is no net capital carried over for revaluation.

We take depreciation to be the change in value of an asset with the passage of time, given anticipated future returns and given rates of discount. If the value of an asset is a function of calendar time, $t$, a vector of expected returns, $Y$, and a vector of discount rates, $R$, depreciation may be viewed as the partial derivative of that value with respect to time, that is, $V=V(t, Y, R)$, and depreciation equals $\partial V / \partial t$. Capital gains then involve those changes in $V$ occasioned by changes in $Y$ and in $R$.

Ideally, where we can specify both expected future returns from capital and rates of discount, we can calculate the true economic depreciation to be applied each year to the updated value of the asset. Estimates of economic depreciation along these lines have been attempted by Mendelowitz (1971) for corporate capital and by Graham and Webb (1979) for human capital. We shall incorporate and endeavor to expand upon some of these latter estimates.

For the main, however, we shall again have recourse to accounting conventions and accept the Bureau of Economic Analysis estimates of straight-line depreciation as incorporated in their latest revisions of capital stock series (utilizing $85 \%$ of Bulletin F lives and their replacement cost bases). I have argued on a number of occasions that the straight-
line depreciation applied by Denison $(1967,1974)$ is a better measure of economic depreciation than the double-rate, declining-balance depreciation employed by Kendrick (1976), Jorgenson (1974), and others (see Eisner 1973, 1975; Christensen and Jorgenson 1973). Evidence in the work of Coen (1975) and the findings of Mendelowitz (1971), Ramm (1971), and Graham and Webb (1979) reinforce that view.

We have thus far been passing over the component of revaluation of capital assets associated with general price inflation. As I indicated earlier, to avoid money illusion we must surely include in income only that portion of capital gains above what is necessary to maintain real capital or real future consumption intact. On the assumption that the elasticity of price expectations is unity, we may then apply current changes in a general price deflator to calculate the value of capital necessary to keep its purchasing power intact. The "net revaluations," which we will take as the capital gains to be included in income and in net capital accumulation, are therefore the change in the value of capital minus both net investment and that portion of the change in value of capital necessary to keep pace with any general increase in the price level.

Thus, while for gross revaluations we have

$$
\begin{equation*}
G R_{t}=K_{t}-K_{t-1}-I N_{t} \tag{1}
\end{equation*}
$$

for net revaluations, as in McElroy (1971),

$$
\begin{equation*}
N R_{t}=K_{t}-\left(\frac{P_{t . e n d}}{P_{t-1, e n d}}\right) K_{t-1}-\left(\frac{P_{t . e n d}}{P_{t}}\right) I N_{t} \tag{2}
\end{equation*}
$$

where
$N R_{t}=$ Net revaluations of the year $t$
$K_{t}=$ Net value of capital at the end of the year $t$
$K_{t-1}=$ Net value of capital at the end of the year $t-1$
$P_{t, e n d}=$ General price deflator at the end of the year $t$
$P_{t-1, e n d}=$ General price deflator at the end of year $t-1$
$P_{t}=$ Average value of general price deflator in the year $t$, and $I N_{t}=$ Net investment in the year $t .{ }^{1}$

After some consideration, we selected as our general price deflator the implicit deflator for gross national product. In terms of a measure that would indicate the appreciation necessary to keep real value intact, it seemed most appropriate to think in terms of the broadest possible set of goods and services for which capital might be exchanged. In one sense this might be restricted to gross domestic product, as in the work of Shoven and Bulow (1975, 1976). But capital can be used in exchange for not only gross domestic product but that component of
gross national product attributed to "rest of the world." In any event, the differences between deflators for gross national product and gross domestic product are trivial.

Net capital accumulation, NCA, will equal the total of net revaluations and net investment, or

$$
\begin{equation*}
N C A_{t}=N R_{t}+I N_{t} \tag{3}
\end{equation*}
$$

We shall be interested in the extent to which consideration of net revaluations alters the picture of net capital accumulation that we have usually had from considering net investment alone. Differences, as I have suggested, may emerge at the national level as well as in particular sectors.

At the national level, aside from net foreign claims, financial assets and liabilities should essentially cancel out, except for the changes in tangible assets to which they relate. Even this may not be entirely so, as debtors and creditors may attach different subjective rates of discount to expected future payments. At the sectoral level, however, and certainly for individual firms and households, changes in the real value of financial assets and liabilities may bulk large.

Among financial assets and liabilities, equities and bonded debt may change real value because of both changes in nominal market values and changes in the value of money. Other financial items, such as bank deposits and currency, will change value only with the price level.

Tangible wealth may be categorized as human and nonhuman. In the nonhuman category we may include what is generally termed reproducible capital; that is, residential and nonresidential structures and producer and consumer durables, along with inventories. In the category of nonreproducible, tangible capital we have land and natural resources.

Unlike Kendrick, who relates tangible human capital to rearing costs, we also count as tangible his "intangible" human capital stemming from education, training, and other human investment that adds to the productive power of the basic human body. Ideally, we might view all output as the services of capital, human and nonhuman, and take the value of human capital as the sum of its discounted future earnings. Since people are neither bred nor educated for earnings alone, however, we cannot expect with any confidence that the supply price of human capital will equal its present value.

We would like to estimate net revaluations of each category of capital held by the sectors of our "Total Incomes System of Accounts" (Eisner 1975, 1978). These involve: enterprises, further subdivided into business corporate enterprises, business noncorporate enterprises, nonprofit enterprises, and government enterprises; households; and government. In many instances the availability or nonavailability of data has forced us either to classify crudely or to combine sectors. This is most particularly
true for households and nonprofit enterprises, which are frequently difficult to disentangle in the accounts, and government enterprises and government, where again data currently available do not permit an easy, reliable separation.

We have had problems with depreciation, alleviated somewhat by the recent BEA replacement-cost, straight-line estimates for structures and equipment. Not all capital has been similarly depreciated, however. Kendrick's human capital stocks, in particular, rely upon double-rate, declining-balance depreciation. We should have liked to employ "economic depreciation," relating to the partial derivative of the value of capital stock with respect to time, as indicated above. In practice we have resorted to straight-line depreciation as the best simple approximation.

### 5.2 Net Revaluations in the United States since World War II

The record of capital gains and losses, or net revaluations in our terminology, is a striking one in the United States economy since World War II. (For views of part of the record see Bhatia 1970; McElroy 1971.)

The mass of tables we have to present are derived in the main from underlying data pieced together from: (1) the Bureau of Economic Analysis (including some as yet unpublished figures) for stocks, investment flows, and depreciation of business plant and equipment and residential capital, business inventories, and government expenditures for equipment and structures; ${ }^{2}$ (2) the Flow of Funds section of the Federal Reserve Board and special tabulations from Helen Tice and then Elizabeth Fogler for financial flows and assets and liabilities by sector, supplemented by estimates of the value of land; (3) investment flows of human capital from Kendrick's Formation and Stocks of Total Capital.

We utilized the following additional sources for several special tables: (4) estimated land values by sectors, including government, for the years 1952 to 1968, from table II-1 (p. 344) of Appendix 2, by Grace Milgram, in Goldsmith (1973); (5) estimates of values of national tangible assets, by categories, for 1952 to 1968 , in current and constant dollars, from Historical Statistics of the United States, Colonial Times to $1970 ;{ }^{3}$ (6) a paper by John Graham and Roy Webb ${ }^{4}$ on the present value of male human capital in 1969, based on Census Public Use Sample data on earnings by age-education cohort, developed into a time series by Graham by applying gross and spendable earnings and population data for the years 1947-75.

The business and residential capital stock data from the Bureau of Economic Analysis are now conveniently in current and 1972 "replacement cost" dollars. Depreciation is consistently taken on a straight-line
basis on the assumption of $85 \%$ of Bulletin F lives. Financial assets and liabiiities in the Flow of Funds accounts or in the special Fogler tabulations were at estimated market value for corporate equities, household equity in unincorporated businesses, direct foreign investment, and life insurance reserves and pension funds. For government and corporate securities and for mortgages, we have converted par values to market by applying New York Stock Exchange bond price indexes or measures of market and par value of government and of corporate securities and of all listed securities, respectively.

Household consumer durables estimates, and government capital stocks, along with other unpublished tables or tables before publication, have been obtained from the Bureau of Economic Analysis through the good offices of John Musgrave. In a number of these instances, as well as with regard to human capital, we have developed our own net investment flows and net stocks by applying perpetual inventory methods with straight-line depreciation. The framework for much of our sectoral analysis regarding nonhuman capital has been the Flow of Funds accounts, supplemented by new estimates on land, and Bureau of Economic Analysis stocks and flows of reproducible capital.

### 5.2.1 Nonhuman Net Worth, by Sector and in Aggregate

Our first set of basic tables, 5.1 through 5.16, offers figures for net worth, net investment, and gross and net revaluations of nonhuman capital for households, business, government, and the total economy, in current and in 1972 dollars. ${ }^{5}$ The household sector here includes personal trusts and nonprofit institutions. Business is taken to comprise noncorporate, corporate nonfinancial, and private financial subsectors. The monetary authority and federally sponsored credit agencies are combined with government. Detailed, item-by-item estimates of net revaluations are offered in tables 5.47 to 5.56 .

It should be noted that "noncorporate" includes all of agriculture, both corporate and noncorporate, except for nonresidential fixed capital on corporate farms, which is counted in the corporate sector. The Flow of Funds section estimates $7 \%$ of agriculture to be corporate.

The household sector includes household equity in corporate and noncorporate enterprise, the first taken at estimated market value of household-owned corporate stock and the second as the net worth of the noncorporate sector. The private financial sector includes the value of its holdings of nonfinancial corporate shares. In aggregating to develop totals for business and the entire economy, these items are therefore netted out of the household and private financial sectors.

Net worth has of course grown enormously since World War II, and in all sectors gross revaluations have accounted for the bulk of that growth. In households, for example, net worth grew from $\$ 677$ billion
to $\$ 5,597$ billion from 1945 to 1977 , an increase of some $\$ 4,920$ billion. ${ }^{6}$ Of this only $\$ 1,938$ billion was accounted for by net investment and $\$ 2,983$ billion, or $61 \%$ of the increase, by gross revaluations.

The increase in prices over the thirty-two-year period as a whole, however, more than offset these gross revaluations. Net revaluations in the household sector totaled- $\$ 231$ billion, an average loss of more than $\$ 7$ billion per year (table 5.1). In 1972 dollars, total household net revaluations were - $\$ 183$ billion, yielding a mean annual loss of $\$ 5.7$ billion (table 5.2).

The mean figures hide a great deal of variance over the years and, as we shall see below, variation by categories of assets and liabilities. The standard deviation of aggregate net revaluations for households is a staggering $\$ 129.0$ billion in current dollars and $\$ 134.1$ billion in 1972 dollars (table 5.21). It is also apparent that while net revaluations were positive in eighteen of the thirty-two years, several sharply negative swings kept the mean less than zero. Thus, the inflation immediately following World War II contributed to very considerable real capital losses in the first few postwar years. The years 1969 and 1970 also saw substantial losses and then the stagflation years of 1973 and 1974 contributed a total of $\$ 748$ billion in negative net revaluations. Indeed, without this episode, and with other net revaluations unchanged, the mean would have run some $\$ 16$ billion annually over the entire period, more than one-quarter the amount of net investment.

The business sector, summarized in tables 5.3 and 5.4 , shows gross revaluations positive in each of the thirty-two years from 1946 to 1975. Net revaluations were positive in twenty-four of the thirty-two years. The constant-dollar total of gross revaluations was almost eleven times that of net investment. The total of net revaluations was 3.4 times the amount of net investment; business sector mean net investment was $\$ 6.6$ billion in 1972 dollars and mean net revaluations were $\$ 22.8$ billion per year.

Consideration of the subcategories of business (in tables 5.5 through 5.10) shows that both gross and net revaluations were distinctly higher for the nonfinancial sectors. Dividing the thirty-two years into six fiveyear subperiods and a final two years, we note that both noncorporate and corporate nonfinancial mean net revaluations were positive in every one of the seven subperiods. The private financial sector, however, suffered total net revaluations of - $\$ 102$ billion, a mean loss of some $\$ 3$ billion per year. These were due largely to declines in the market value of bonds and mortgages, occasioned by rising interest rates, owing partly to inflation, and further declines in their real value owing directly to inflation. Along with a mean loss of $\$ 4$ billion in 1972 dollars on holdings of equity in nonfinancial corporations, these asset declines somewhat outweighed declines in the real value of liabilities (tables
5.10 and 5.54). We may have here a clue to the dominant concern with inflation among the financial community. Their negative net revaluations counterbalanced more than half of net investment.

The big gainer by our calculations-perhaps no surprise to traditional, objecting conservatives-has been government. Net revaluations were positive for our government sector, even with the inclusion of federally sponsored credit agencies and the monetary authority, in no less than twenty-nine of the thirty-two years. The string of net capital gains has been unbroken since 1961. Over the entire thirty-two-year period, mean net revaluations averaged $\$ 21$ billion per year (table 5.11).

The net worth of the government sector was $\$ 17.6$ billion at the end of 1945 . It grew to $\$ 1,070$ billion at the end of 1977 , despite negative net investment of $\$ 149$ billion $^{7}$ over the intervening years, as gross revaluations were a positive $\$ 1,201$ billion. Even after the inflation allowance, we come up with a total of positive net revaluations of $\$ 675$ billion. In 1972 dollars the total was $\$ 844$ billion and the mean was $\$ 26$ billion (table 5.12). We can note in tables 5.55 and 5.56 the particular contributing factors but may observe now more generally that the government sector gained from huge declines in the real value of its debt, both because of the direct effect of inflation and because of the increases in interest rates that lowered its nominal market value.

In table 5.13 we report sums of the individual sector magnitudes. Capital gains turn out not to have been a transient factor for which bad years canceled out the good. Net revaluations for the total of our domestic sectors were positive in twenty-three of the thirty-two years; their means were positive in five of the seven subperiods and only very slightly negative in the others. Over the entire thirty-two-year stretch, gross revaluations amounted to $\$ 6,357$ billion, some three times the total of $\$ 2,124$ billion of net investment. But even after allowance for inflation, the total of sector net revaluations came to $\$ 1,134$ billion, a mean of $\$ 35$ billion per year, or $\$ 39$ billion in 1972 dollars, as shown in table 5.14.

Tables 5.15 and 5.16 offer economy totals of net worth, net investment, and gross and net revaluations, eliminating the double-counting stemming from household and private financial ownership of noncorporate and corporate nonfinancial business. Tables 5.17 and 5.18 offer matching sector detail for net investment, while tables 5.19 and 5.20 do so for net revaluations. Total gross revaluations are reduced to $\$ 4,706$ billion but are still some 2.39 times the now $\$ 1,967$ billion total of net investment. Total net revaluations of non-human capital amounted to $\$ 917$ billion, a mean of $\$ 28.7$ billion per year, or $\$ 27.2$ billion in 1972 dollars. Accumulation or growth in the form of capital gains after allowance for inflation is thus almost half the amount of net investment.

If real increases in net worth are to be taken as net saving, we understate saving seriously when we exclude net revaluations.

While total net revaluations are positive, the differences among sectors and over time are substantial. We have already noted that two of the sectors-households and private financial-are on balance losers over the thirty-two-year period. Standard deviations of annual net revaluations are high in all the sectors. The correlations between the household time series and those of the sectors other than noncorporate are negative, as is that of private financial with government, as shown in table 5.21. These negative correlations reflect the fact that the financial assets of one sector are frequently the liabilities of another. Inclusion with households of such large holders of financial assets as personal trusts and nonprofit institutions serves to accentuate negative correlations of that sector with others.

There are substantial positive correlations among the sectors-corporate, noncorporate, and government-experiencing capital gains. These reflect common movements in values of tangible assets as well as of bonded liabilities.

### 5.2.2 Tangible Nonhuman Capital

Estimates of net revaluations of tangible, nonhuman capital are striking. Their sums are distinctly positive over our thirty-two-year period for fixed nonresidential and residential capital and for land. They are negative only for consumer durables.

Mean net revaluations of fixed nonresidential business capital were $\$ 4.2$ billion per year for corporations, $\$ 0.8$ billion per year for noncorporate enterprises, and $\$ 0.3$ billion for nonprofit institutions, as may be seen in tables 5.23, 5.24, and 5.25. Thus mean capital gains on fixed nonresidential business capital for all three sectors combined (table 5.26 ) amounted to $\$ 5.4$ billion per year, adding more than $30 \%$ to the net investment mean of $\$ 17.5$ billion.

Net revaluations of nonresidential capital were positive for the total of all sectors in twenty-two out of thirty-two years and in six out of the seven subperiods. Seven of the ten negative annual net revaluations came in succession in the years 1958 through 1964. Net revaluations have been positive in each of the years since then.

Gross revaluations over the thirty-two-year period substantially exceeded net investment: $\$ 703$ billion to $\$ 416$ billion for corporations, $\$ 182$ billion to $\$ 98$ billion in the noncorporate sector, $\$ 73$ billion to $\$ 47$ billion for nonprofit institutions, and $\$ 958$ billion to $\$ 561$ billion for all business sectors combined. The corresponding net revaluations were $\$ 135$ billion for corporations, $\$ 27$ billion for noncorporate enterprises, $\$ 9$ billion for nonprofit institutions, and $\$ 172$ billion in total.

Net revaluations for fixed residential capital (excluding land) are about the same. As can be seen in tables 5.27, 5.28, and 5.29, gross revaluations exceeded net investment both for owner-occupied and tenant-occupied residential capital. Capital gains net of inflation totaled $\$ 182$ billion for all fixed residential capital, just over one-third of net investment of $\$ 543$ billion. Total net revaluations of fixed residential capital were negative in nineteen out of the thirty-two years but were positive in all but three of the years since 1966 and totaled $\$ 152$ billion in the years 1976 and 1977. The years 1975 to 1977 indeed fully accounted for the positive balance over the entire postwar period.

Net revaluations on business inventories averaged out to be just about zero, as shown in table 5.30.

Major capital gains are to be found in privately owned land. Net revaluations totaled $\$ 531$ billion, averaging more than $\$ 16$ billion per year, and were positive in all years except 1946 and 1947, 1969 to 1971, and 1975, as is shown in table 5.31. It may well be argued, of course, that much of the increased value of land stems from land development or investment in land. Our assumption that investment in land is zero hence classifies all increases in land value as revaluations or capital gains. That assumption, however, is consistent with the definition of investment in the BEA income and product accounts.

A somewhat different set of revaluations by sector, derived from estimates of land values put together by Grace Milgram, is found in table 5.32. While the yearly figures for privately held land differ significantly from those in Table 5.31, based upon Federal Reserve Flow of Funds data, the general picture is similar. From Milgram's estimated land values, net revaluations in land were positive in each of her five sectors for all the years from 1953 through 1968 for which her data were available. By her estimates, the value of land rose from $\$ 201$ billion at the end of 1952 to $\$ 726$ billion at the end of 1968 , a total gross revaluation of $\$ 525$ billion. Net revaluations in land over this period amounted to $\$ 358$ billion, of which $\$ 135$ billion was for nonfarm households, $\$ 16$ billion was in nonprofit institutions, $\$ 65$ billion in unincorporated business plus agriculture, $\$ 64$ billion in nonfarm corporations, and $\$ 78$ billion in the government sector. Mean net revaluations over the period 1953 to 1968 were $\$ 8.4$ billion in nonfarm households, $\$ 1.0$ billion in nonprofit institutions, $\$ 4.0$ billion each in the noncorporate and corporate sectors, and $\$ 4.9$ billion in government, for a total of $\$ 22.4$ billion per year in all sectors combined.

### 5.2.3 Net Revaluations, Saving, and Capital Accumulation

It is informative to consider capital gains and losses in relation to traditional measures of saving and investment. Beginning with house-
holds (again including personal trusts and nonprofit institutions), negative mean net revaluations of $\$ 7.2$ billion over the years 1946 to 1977 offset $23 \%$ of mean personal saving of $\$ 31.3$ billion (table 5.33). The huge negative revaluations of 1973 and 1974, totaling $\$ 747$ billion, almost completely wiped out the $\$ 785$ billion of personal saving in all the years from 1946 to 1974. The losses related primarily to the combination of a stock market decline and inflation. While the mean ratio of personal saving to disposable income of $6.2 \%$ contrasted with a mean ratio of net revaluations to disposable income of $-0.2 \%$ over the entire 1946 to 1977 period, there were substantial fluctuations, particularly in the latter. The mean net revaluations ratios were some $50 \%$ more than the mean personal saving ratios for the subperiods from 1951 to 1955 and from 1961 to 1965.

Another view of net revaluations may be found with conversion of all the saving data to 1972 dollars, using the implicit price deflator for fixed investment. As is shown in table 5.34, mean net revaluations in these 1972 dollars were - $\$ 5.7$ billion, offsetting almost one-sixth of mean personal saving of $\$ 35.8$ billion.

The role of net revaluations in a comprehensive measure of capital accumulation comes forth clearly in table 5.35, and corresponding figure 5.1, where we examine tangible assets in particular. Tangible net investment--the acquisition of residential and nonresidential capital, nonprofit investment in plant and equipment, household investment in durable goods, and government fixed investment, all net of depreciation, plus investment in business inventories and investment in land-totaled $\$ 1,990$ billion from 1946 to 1977, as against only $\$ 1,372$ billion for the BEA's net private domestic investment. In addition, net revaluations of tangible capital amounted to $\$ 931$ billion. Thus, tangible net accumulation of nonhuman capital came to $\$ 2,920$ billion. The means per year were $\$ 43$ billion for net private domestic investment, $\$ 62$ billion for tangible net investment of all sectors, $\$ 29$ billion for net revaluations and $\$ 91$ billion for net capital accumulation.

Some confirmation of these results for tangible capital may be found by estimating gross revaluations and net revaluations from the data on national tangible assets, provided in both current prices and constant (1958) prices for the years 1952 to 1968 in the Census Bureau's Historical Statistics of the United States, Colonial Times to 1970. Calculations from these data indicate total net revaluations of $\$ 264$ billion over the sixteen years, with a mean annual figure of $\$ 16.5$ billion, as is shown in table 5.37. Net revaluations were somewhat negative, however, for reproducible assets alone, running to an annual average of $-\$ 5.5$ billion, with a positive contribution of some $\$ 22$ billion coming from land. The negative net revaluations on reproducible assets stemmed from sub-

Fig. 5.1 Comparative movements of conventional investment and tangible capital formation, 1946-77. From table 5.35.
stantially negative figures on inventories and consumer and producer durables. Net revaluations for structures were, as in our own data, positive.

### 5.2.4 Human Capital

An analysis of capital revaluations and capital accumulation is incomplete unless consideration is given to human capital. By various measures, indeed, the amounts of human capital and human capital accumulation considerably exceed the magnitudes for nonhuman capital.

Information on earnings over the life cycle permits estimates of human capital as the present value of future labor earnings. Utilizing census public-use sample data with earnings by age-education cohort, Graham and Webb (1979) have applied a variety of discount rates to estimate the value of male human capital in 1969.

For illustrative purposes, at least, we have taken their estimates with a $7.5 \%$ discount rate, using both gross earnings and spendable earnings as a basis for development of time series for net stock. These have been accomplished by Graham by adjusting the 1969 estimates back to 1947 and forward to 1975 in accordance with reported changes in gross earnings and in spendable earnings as well as in population. Using the smaller spendable earnings series, estimates of the value of male human capital show it growing from $\$ 1,928$ billion at the end of 1947 to $\$ 9,133$ billion at the end of 1975 (table 5.38). "Gross" accumulation of human capital by this measure thus amounted to $\$ 7,205$ billion over the twenty-eight-year period, with an annual mean of $\$ 257$ billion. Applying our usual formulations to abstract from increases in the net stock of capital necessary to keep pace with inflation, we come up with net capital accumulation amounting to $\$ 2,249$ billion from 1948 to 1975, a mean of $\$ 80$ billion per year.

After this exercise in present value estimates of male human capital, we utilized the Kendrick series on human capital formation to produce replacement cost estimates of net stocks of human capital in both constant and current dollars. We used Kendrick's flows rather than his stock estimates because we considered his declining-balance depreciation assumptions inappropriate.

Although Kendrick had different assumed lives for various components of human capital, his estimates revealed an implicit average life of human capital of somewhat over fifty years. We took Kendrick's aggregate flows of human capital in constant dollars and applied straight-line depreciation with a fifty-year life throughout to derive net capital stocks in constant dollars, shown (converted to base 1969) in table 5.40. We used the implicit price deflators for gross investment in human capital calculated from Kendrick's aggregate flows in current and constant dollars to reflate the constant-dollar net capital stock series
to current replacement-cost dollars. The constant-dollar depreciation was similarly reflated so that net investment and gross revaluation could be distinguished in our usual manner.

We then find, as shown in table 5.39, that net investment in human capital totaled $\$ 1,732$ billion from 1946 through 1969 , with gross revaluations of $\$ 1,200$ billion accounting for the rest of the increase in the value of human capital. Net revaluations, however, were much less, amounting to $\$ 145$ billion. Total net capital accumulation, the sum of net investment and net revaluations, was $\$ 1,877$ from 1946 through 1969, implying a mean annual net capital accumulation of $\$ 78$ billion, ${ }^{8}$ of which $\$ 72$ billion was net investment and $\$ 6$ billion was net revaluations. In constant 1969 dollars the picture was similar, but with figures generally higher. Thus mean net investment was $\$ 95$ billion, mean net revaluations were $\$ 8$ billion and mean net capital accumulation was $\$ 103$ billion (table 5.40 ).

The various components of accumulation of nonhuman and human capital may usefully be juxtaposed. We may view all of human capital as owned by households and compare and combine household investment revaluations and total capital accumulation of nonhuman capital and the corresponding series for human capital. Over the period 1946 to 1969 for which our human capital calculations can also be made from the underlying Kendrick data, we find, as is revealed in table 5.41 , that the $\$ 1,732$ billion net investment in human capital was more than 1.75 times the $\$ 971$ billion of household net investment in nonhuman capital. The mean annual figure of $\$ 72$ billion for net investment in human capital contrasted with $\$ 40$ billion for nonhuman capital.

Net revaluations of nonhuman capital over this period were greater, however. Their total of $\$ 272$ billion (with a mean annual figure of $\$ 11$ billion) considerably exceeds the total human capital net revaluations of $\$ 145$ billion noted above. The estimate of net nonhuman capital accumulation, of $\$ 1,242$ billion (mean of $\$ 52$ billion), is markedly less than the $\$ 1,877$ billion for human capital. Net accumulation of both nonhuman and human capital amounted to $\$ 3,119$ billion, with a mean of $\$ 130$ billion.

Put in constant (1969) dollars again, the relative excess of net accumulation of human capital over that of nonhuman capital is even greater. Human capital formation of $\$ 2,465$ billion was about 1.65 times the nonhuman accumulation of $\$ 1,492$ billion. In the current dollar series, human capital accumulation was only 1.51 times nonhuman capital accumulation, the difference being considerably accounted for by the relatively larger effect of negative constant-dollar net revaluations of nonhuman capital just after World War II.

Finally, we may usefully compare, in table 5.43 and corresponding figure 5.2 , total net formation of nonhuman and human capital with
Fig. 5.2
the BEA series of net private domestic investment. Net investment according to the narrow BEA concept, excluding government and household investment (except owner-occupied homes) and also excluding net revaluations, was $\$ 801$ billion from 1946 through 1969. Our total net tangible formation of nonhuman capital, by contrast, was $\$ 1,427$ billion. We have of course, included investment by households and government and net revaluations on reproducible assets and land.

To this we may wish to add the $\$ 1,877$ billion of net formation of human capital. Thus, nonfinancial capital formation was $\$ 3,304$ billion, more than four times net private domestic investment. Mean annual net private domestic investment from 1946 to 1969 was $\$ 33$ billion. Mean net tangible nonhuman capital formation was $\$ 59$ billion. With the mean human capital formation of $\$ 78$ billion, mean total net capital formation was $\$ 138$ billion. If these estimates are anywhere near reasonable, one cannot but reflect that, whatever the role of capital formation, what the Bureau of Economic Analysis reports by way of net private domestic investment is a literally minor component of the total.

This reflection is sustained by examination of the distribution of net (nonhuman) capital accumulation of tangible assets by sector for all the years 1946 to 1977 (table 5.44). Including both net investment and net revaluations, ${ }^{9}$ the total, we may recall, was $\$ 2,920$ billion, and the annual mean was $\$ 91$ billion. Of this, some $\$ 498$ billion was associated with noncorporate enterprise, $\$ 767$ billion with the corporate nonfinancial sector, and $\$ 45$ billion more with the private financial sector. All business tangible capital accumulation thus came to $\$ 1,310$ billion, only $45 \%$ of the total.

Household capital formation of $\$ 1,121$ billion was some $38 \%$ of the tangible total, and government capital formation of $\$ 489$ billion was another $17 \%$. Mean net capital formation of tangible assets over the years 1946 to 1977 was $\$ 35.0$ billion for households, $\$ 15.6$ billion for noncorporate enterprises, $\$ 24.0$ billion for corporate nonfinancial enterprises, $\$ 1.4$ billion for the private financial sector, and $\$ 15.3$ billion for government.

### 5.2.5 Composition of Net Revaluations

Much of the story on capital gains and losses is in their distribution. All sectors gained, in varying degree, on their total holdings of tangible assets-that is, of land and reproducible capital. On financial assets and liabilities, what we call nontangibles, if we exclude the value of business equity owned by households and financial institutions, net revaluations for the entire economy come close to zero. The mean negative figure of $-\$ 0.4$ billion is presumably a net loss on dealings with the rest of the world. As is seen, however, in tables 5.45 and 5.46 , in
current and 1972 dollars respectively, the near-zero total reflects losses of more than $\$ 700$ billion by households, matched by gains of roughly this amount in the noncorporate, corporate financial, and government sectors.

First, with regard to households (tables 5.47 and 5.48 ), while the net revaluations on owner-occupied housing in 1972 dollars, for example, came to a modest mean of $\$ 3.5$ billion, the associated gain in net revaluations on household mortgage debt was $\$ 10.3$ billion. We have already observed that all sectors were substantial gainers on land; for households, the mean gain in 1972 dollars was $\$ 6.8$ billion. Households were losers in consumer durables, however, at an average rate of $\$ 7.9$ billion per year.

Households lost most heavily, as may be imagined with long-run inflation, in their holdings of money, at an average rate of $\$ 19.2$ billion in 1972 dollars on the total of currency and demand and time deposits. They also lost heavily, to the amount of $\$ 5.1$ billion per year, on United States government securities and about $\$ 2.7$ billion on state and local obligations and corporate and foreign bonds. Households were major losers indirectly, if not directly, in life insurance and pension funds, which showed mean net revaluations of $-\$ 10.8$ billion from 1946 to 1977.

Despite massive fluctuations in value, corporate equities yielded a mean annual gain to households of $\$ 4.5$ billion in 1972 dollars. Equity in noncorporate business shows a very substantial positive net revaluation, totaling $\$ 377$ billion and averaging $\$ 11.8$ billion per year.

It may be reasonable to infer with regard to the household sector that gains came primarily to homeowners (who generally had mortgage debts), to corporate stockholders, and to independent proprietors. It is probable that the majority of relatively lower-income households tended to be net losers, with investments primarily in life insurance and pension funds, savings accounts, and government saving bonds. Egalitarian considerations might suggest these points as an argument for eliminating government restrictions on payment of interest by banks and saving institutions. They might also suggest the advisability of offerings of indexed government bonds that would permit both individuals and their pension funds to protect themselves against losses in the real value of securities because of inflation.

It might also be noted that reduction of taxes on capital gains increases the disparity of tax treatment and widens the dispersion in the total of ordinary after-tax income and net revaluations. Those with savings accounts and corporate and federal government bonds have interest income that is fully taxed and have suffered real nondeductible capital losses. By contrast there were relatively lightly taxed capital gains on land, homes, and mortgage debt, and on corporate equity.

In the noncorporate sector, detailed in tables 5.49 and 5.50 , mean total net revaluations were $+\$ 11.8$ billion in 1972 dollars. The substantial mean annual net revaluation of $\$ 8.9$ billion in 1972 dollars in land may well reflect capital gains on farms, which are here all lumped with noncorporate enterprises. Somewhat lesser gains on residential structures and nonresidential plant and equipment totaled $\$ 36$ billion, coming to an annual average of $\$ 1.1$ billion. The noncorporate sector turned up a loser, however, to the amount of $\$ 1$ billion per year, on currency and demand deposits.

The corporate nonfinancial sector was a net gainer, in total, of $\$ 405$ billion over the thirty-two-year period, for an average positive net revaluation of $\$ 12.6$ billion in 1972 dollars. It actually gained in tangible assets a total of $\$ 208$ billion- $\$ 134$ billion in residential structures and nonresidential plant and equipment, $\$ 61$ billion in land, and $\$ 13.5$ billion on inventories. The corporate nonfinancial sector was a major loser, however, in financial assets, to a total of $\$ 405$ billion in 1972 dollars, of which $\$ 68$ billion could be attributed to currency and deposits, $\$ 27$ billion to United States government securities, $\$ 14$ billion to commercial paper, and a quite substantial $\$ 206$ billion to consumer and trade credit.

The corporate nonfinancial sector's gains on the liability side totaled $\$ 601$ billion, for an annual average of $\$ 18.8$ billion in 1972 dollars. These stem considerably from "corporate and foreign bonds" where the total gain was $\$ 184$ billion, from mortgage debt with a total gain of $\$ 94$ billion, from "other loans" with a total of $\$ 126$ billion, and from net trade debt with a total of $\$ 156$ billion. All this is shown in sum and year by year in table 5.52.

The mean annual negative net revaluations of - $\$ 5.7$ billion in 1972 dollars in the private financial sector is the result, as is spelled out in table 5.54, of $\$ 1,517$ billion of negative net revaluations in financial assets almost balanced by $\$ 1,327$ billion of negative net revaluations in liabilities. By our reckoning, in the years from 1946 to 1977 the private financial sector lost $\$ 22$ billion on assets in the form of deposits and currency, $\$ 54$ billion on interbank claims, $\$ 131$ billion on corporate shares, $\$ 243$ billion on United States government securities, $\$ 92$ billion on state and local obligations, $\$ 181$ billion on corporate and foreign bonds, $\$ 402$ billion on mortgages, $\$ 318$ billion on "other loans," $\$ 23$ billion on security credit, $\$ 4$ billion on trade credit, and $\$ 46$ billion on miscellaneous assets. On the other side, negative net revaluations among liabilities caused gains of $\$ 761$ billion on deposits and currency, $\$ 306$ billion on life insurance and pension reserves, $\$ 13$ billion on interbank claims, $\$ 37$ billion on investment company shares, $\$ 23$ billion on corporate and foreign bonds, $\$ 14$ billion on security debt, $\$ 3$ billion on taxes payable, and $\$ 117$ billion on miscellaneous liabilities. Our measure of gains in tangible assets for the private financial sector was small,
amounting to only $\$ 1$ billion on residential and nonresidential capital and $\$ 5$ billion on land.

The government sector, we may recall, was a substantial gainer, with total net revaluations amounting to $+\$ 844$ billion in 1972 dollars for 1946 to 1977. As is shown in table 5.56, there were gains of $\$ 927$ billion from negative net revaluations of government liabilities. These amounted to $\$ 148$ billion for state and local obligations, $\$ 592$ billion for United States government securities, $\$ 12$ billion for trade debt, and $\$ 40$ billion for life insurance and pension funds. Recalling that federally sponsored credit agencies and the Federal Reserve are included in the government sector, we also note $\$ 75$ billion of gains on currency, demand deposit, and time deposit liabilities, and $\$ 45$ billion more on vault cash and member bank reserves. Finally, $\$ 14$ billion was gained on miscellaneous liabilities. The government sector lost $\$ 57$ billion in 1972 dollars on its financial assets in currency and deposits, $\$ 50$ billion on gold, SDRs and foreign exchange, some $\$ 113$ billion on holdings of United States government securities, $\$ 4$ billion on state and local obligations, $\$ 50$ billion on mortgages, $\$ 64$ billion on other loans, $\$ 25$ billion on taxes receivable, $\$ 5$ billion on trade credit, and $\$ 8$ billion on miscellaneous assets. In tangible assets, the government sector gained some $\$ 144$ billion on structures, plant, and equipment, and $\$ 173$ billion on land. It lost $\$ 22$ billion on inventories.

### 5.3 Summary and Conclusions

We have distinguished revaluations of capital, net of general pricelevel changes, for inclusion in measures of income and capital accumulation. We have then proceeded to estimate net revaluations in the United States economy from 1946 through 1977 and to present the results in varying detail, along with a number of series for net worth or net capital stocks, net investment, gross revaluations, and related data from our conventional accounts.

We have prepared estimates on major sectors of the economy, and for human and nonhuman capital, the latter broken down in some detail for both tangible assets, including land, and for financial assets and liabilities.

Net revaluations or capital gains turn out on balance, despite considerable fluctuations, particularly in certain financial assets and liabilities, to be substantially positive. Capital gains, at least by our measure in this thirty-two-year period, and even after allowance for general inflation effects, have not been completely offset by capital losses.

On tangible assets alone, mean net revaluations over the years from 1946 to 1977 were $+\$ 29.1$ billion (or $+\$ 28.0$ billion in 1972 dollars). Tangible net investment aside from revaluations showed a mean figure
of $\$ 62.2$ billion. These magnitudes relate to all tangible nonhuman capital, in government and households as well as in business, and include net revaluations of land. An interesting rough comparison is to be found in the mean figure of $\$ 42.9$ billion for net private domestic investment in the conventional income and product accounts. Our mean tangible net capital accumulation by contrast is $\$ 91.3$ billion. Total tangible capital accumulation from 1946 through 1977 by our measure was $\$ 2,920$ billion. Total net private domestic investment reported by the Bureau of Economic Analysis was $\$ 1,372$ billion.

Measured net revaluations by our methods were relatively less in the case of human capital, but total mean net capital accumulation was large. For the period 1946 to 1969 , for which we were able to make reasonably comparable estimates, mean net private domestic investment was $\$ 33$ billion, mean net tangible capital formation of nonhuman capital was $\$ 59$ billion, and mean formation of human capital was $\$ 78$ billion.

Measured in 1969 dollars and including all household assets, tangible and financial, we find that mean household nonhuman capital accumulation came to $\$ 62$ billion, of which $\$ 11$ billion was attributed to net revaluations. Mean human capital formation was estimated at $\$ 103$ billion, of which $\$ 8$ billion was attributed to net revaluations.

The sectoral breakdown indicates major gains by government, substantial positive net revaluations for nonfinancial business, both corporate and noncorporate, and some losses on balance in the financial sector. Households (including personal trusts and nonprofit institutions) also ended up net losers, but variations over time were great and the aggregates subsumed wide differences by category of assets and liabilities. In general, holders of land, owners of homes (especially because of their gains on mortgage debt liabilities), owners of unincorporated business, and, until recently, owners of corporate equity, tended to do well. Those households, probably constituting the majority, who were not relatively well situated in terms of these kinds of investments, tended to be losers because of the substantial negative net revaluations on currency, demand and time deposits, and life insurance and pension funds.

The collection and processing of these data has turned into a mammoth job for the dedicated but small crew of research associates working with me. Updating and taking advantage of more and improved data since the original version of this paper was presented to the 1976 Toronto conference has in itself become a formidable undertaking. As more government resources and those of other researchers are applied to update and improve upon basic relevant data, our own estimates may well be further corrected and sharpened. Our reported gains and losses on financial assets and liabilities depend upon a compounding of data
from the Flow of Funds section of the Federal Reserve Board and our own security price indexes and are calculated at highly aggregative levels. The estimates of land values are also highly aggregative and likely to be susceptible of substantial improvement.

As for our estimates of net revaluations of tangible assets, it must be recognized that they depend critically on "replacement cost" calculations rather than market valuations, on the one hand, and on the relation between movements of the implicit price deflators for capital goods and of the general price deflator on the other. Thus, positive net revaluations in tangible assets arise essentially where their prices increase more rapidly than does our GNP implicit price deflator.

That this last has proved true should not be a great surprise. We should generally have been aware of major gains in land prices, the result of direct development and positive externalities from other investment as well as increasing scarcity. And capital goods prices, at least by conventional measures, have tended to rise more than those of other goods.

For human capital, which accounts for such a major portion of total accumulation, our estimated net revaluations appear less, but here the feactors remain buried, at least for the moment, in the composition of the implicit price deflators for human capital investment that we have derived from Kendrick's flows.

The magnitude of net revaluations over the thirty-two-year period we have examined, $\$ 869$ billion in 1972 dollars in nonhuman capital, suggests that we ignore them at some peril in measures of income, saving, and capital accumulation. At the household level, the distribution of personal income will reflect quite imperfectly the distribution or accrual of economic power and the means of economic well-being. Measures of saving and of tangible capital accumulation, so relevant in the perennial choices of individuals and society between the present and the future, should take into account capital gains (and losses) along with all lkinds of investment, in human as well as nonhuman capital, in governinent and household sectors as well as in business. Reform of accounting procedures to eliminate the distorting effects of inflation should include revaluations of existing assets and liabilities corresponding to alterations in the values of flows that reflect changes in relative prices and in the general price level.

Consumption and saving must depend upon all income. The value of current production must relate to the current value of all capital. While inuch can certainly be done to improve upon the series presented here, one may hope to test their usefulness and relevance even in their csurrent form by introducing them as arguments in the functions for consumption, investment, production, and economic growth that are properly of ultimate concern.

Table 5.1 Net Worth, Net Investment, Gross and Net Revaluations of Nonhuman Capital, Households (Billions of Dollars, 1946-77)

Source: Calculated from series F349-364, "National Tangible Assets in Current Prices," and F365-376, "National Reproducible Assets in Constant (1958) Prices," both excluding Alaska and Hawaii, of U.S. Department of Commerce, Bureau of the Census, Historical Statistics of the United States, Colonial Times to 1970, Part 1 (Washington, D.C.: GPO, 1975).
a Constant-dollar net stock "estimates derived by 'perpetual inventory' method that is intended to reflect reproduction cost of different types of assets. Estimates are obtained by: (a) reducing each year's gross capital expenditures in current prices to 1958 price level by means of appropriate construction cost or wholesale price indexes; (b) depreciating gross capital expenditures in accordance with an assumed length of life for different types of assets, thus obtaining net capital expenditures for each year in 1958 prices; (c) cumulating net capital expenditures for as many years backwards as corresponds to the assumed length of life of the type of asset involved".

Current-dollar net stock "estimates obtained by multiplying the constant dollar figures shown in series F365-376 by the appropriate price index for current year." We then calculate net investment in constant dollars as the first difference of constant-dollar net capital stocks reported in series F365-376. Reflation to current-dollar net investment is accomplished by applying implicit deflators calculated by dividing the current dollar stocks of series F349-364 by the constant dollar stocks of series F365-376.
${ }^{\text {b }}$ Current-dollar stock estimates are based on book values. Constantdollar stock estimates reflect book values reduced by means of wholesale price indexes.
${ }^{\text {e }}$ Estimates are based on census or similar data. For other private land, estimates are derived by application of rough ratios of land to structure values for different types of real estate. Excludes subsoil assets." We assume zero investment and depreciation in land.

| 1977 | 98.430 | 93.130 | 96.520 |

## Appendix: Sources and Methods

Most of the summary tables dealing with nonhuman capital, including all of tables 5.1 to 5.31 and 5.44 to 5.46 and parts of others, are drawn from, or based upon data underlying, tables 5.47 to 5.56 . The latter present net revaluations in detail for each of our five major sectorshouseholds, noncorporate, nonfinancial corporate, private financial, and government, in current and in 1972 dollars. Sources and methods are therefore first reported for tables 5.47 to 5.56 , which are then used as references for the earlier tables.

Net revaluations are calculated, as shown in the text (eq. 2), from data on end-of-year stocks, K, net investment, I, and GNP implicit price deflators. Net investment in financial assets and liabilities was generally taken as the first difference of their stocks (in current dollars, and before the application of bond price indexes, BPI, to convert from par to market value when applicable). For reproducible tangible assets, net investment was calculated as: (a) gross investment minus depreciation charges, or (b) the first difference of constant-dollar net stocks converted to current dollars by their own implicit stock deflator. Investment in land was assumed to be zero.

Current-dollar figures are generally presented in odd-numbered tables, and 1972 dollar results are shown in even-numbered tables. Unless otherwise indicated, the implicit price deflator for fixed investment is used to convert from current to 1972 dollars.

## Table 5.47, Households, Current Dollars

Total tangible assets $=$ total reproducible assets + land
Total reproducible assets $=$ residential structures + nonprofit plant and equipment + consumer durables
Owner-occupied housing
K-Owner-occupied nonfarm-Musgrave [5.5.a] ${ }^{1}$
I-Owner-occupied nonfarm-Musgrave [5.6.a]
Gross investment minus depreciation [5.5.a]
Nonprofit fixed capital
Residential structures
K-Musgrave [5.7, current dollars]
I-First differences of constant dollar net stocks, Musgrave [5.7, 1972 dollars], converted to current dollars by multiplying by the implicit
price deflator for residential structures, SCB [11.a, table 7.1]
Nonresidential plant and equipment
K-Musgrave [5.1.a, current dollars]

[^2]I-Musgrave [5.1.a, historical cost, gross investment] minus [5.1.a, current-dollar depreciation]
Consumer durables
K-Musgrave [8]
I-Gross investment minus depreciation [8]
Land
K-FED [7]
Currency, demand deposits, and time deposits
K-FED [7]
U.S. government securities

K-FED [7] times BPI for U.S. and state and local governments
State and local obligations
K-FFD [7] times BPI for U.S. and state and local governments Corporate and foreign bonds

K-FED [7] times BPI for corporate and foreign bonds Commercial paper

K-FED [7], open market paper plus money market fund shares Corporate equities

K-FED [7]
I-FED [7], flow item, net purchase of corporate shares
Mortgages
K-FED [7] times BPI for all listed bonds
Life insurance and pension funds
K-FED [7]
I-FED [7], flow item
Noncorporate equities
K-Net worth, noncorporate sector
I-Net investment, noncorporate sector
Miscellaneous assets
K-FED [7], miscellaneous assets plus security credit
Mortgage debt
K--FED [7], home and other mortgages, times BPI for all listed bonds
Other loans and credit
K-FED [7], installment consumer credit, other consumer credit, bank loans n.e.c., and other loans
Trade credit
K-FED [7]
Miscellaneous liabilities
K-FED [7], security credit and deferred and unpaid life insurance premiums

## Table 5.48, Households, 1972 Dollars

Table 5.47 converted to 1972 dollars using implicit price deflators for fixed investment, SCB [11.a, table 7.1]

Table 5.49, Noncorporate Nonfarm, and Farm, Current Dollars
Residential structures and nonresidential plant and equipment
Residential structures
K-SCB [11.b] Noncorporate, table 6, minus Musgrave [5.5.a] and Musgrave [5.7], current dollars
I-First difference of constant-dollar net stocks, SCB [11.b.], noncorporate, converted to current dollars with residential structures implicit price deflators, SCB [11.a., table 7.1] minus (net investment, owner-occupied nonfarm residential [5.6.a, 5.5.a.] and net investment, nonprofit residential capital [5.7] as computed in table 31).

Nonresidential plant and equipment
K-Musgrave [5.1.b], current-dollar net stocks, minus Musgrave [5.1.a], current-dollar net stocks.
I-Musgrave [5.1.b], historical dollars, gross investments minus [5.1.b], current dollars, depreciation; minus Musgrave [5.1.a], historical dollars, gross investments minus [5.1.a] current dollars, depreciation.
Fixed nonresidential corporate farm capital is included in the nonfinancial corporate sector. Flow of Funds data, utilized for the items below, however, include all of farm business with noncorporate.
Inventories

Net revaluations from table 5.1, col. 5

Table 5.34, Personal Income and Saving, 1972 Dollars
Disposable personal income from SCB [11.a, table 2.1]. Personal saving, from table 5.33, was converted to 1972 dollars using the implicit price deflator for personal consumption expenditures [SCB, 11.a, table 7.1], and the deflator for fixed investment was used for net revaluations.

Table 5.35, Investment and Capital Accumulations, Current Dollars
Net private domestic investment from SCB [11.a, table 5.2].
Tangible net investment from summing net investments on tangible assets from tables 5.47, 49, 51, 53, and 55.
Tangible net revaluations from summing net revaluations on tangible assets from tables $5.47,49,51,53$, and 55.
Tangible net capital accumulation $=$ tangible net investment + net revaluations
Table 5.36 and 5.37, Tangible Assets
Sources and methods indicated in footnotes to tables 5.36 and 5.37.

## Table 5.38

Net capital stock:
From gross earnings-using the 1969 figure from Graham-Webb [2], $K_{69}=\$ 7,148$ billion, then:

$$
K_{t}=K_{69} \quad \frac{P o p_{t}}{P o p_{t}} \quad \frac{G E_{t}}{G E_{69}} .
$$

where Pop $_{t}=$ male population size in year $t$, from Historical Statistics [10, table A24].
and $G E_{t}=$ average annual gross earnings in year $t$, from Economic
Report [12, table B-29, p. 205].
From spendable earnings-using the 1969 figure from Graham-Webb [2], $K_{69}=\$ 5,960$ billion, and spendable earnings rather than gross earnings from Economic Report [12, table B-29, p. 205], otherwise similar to method for gross earnings.
"Gross" capital accumulation (GCA):
From gross earnings--GCA $=K_{t}-K_{t-1}$, where $K_{t}$ is net stock from gross earnings in year $t$ (col. 2).
From spendable earnings- $G C A_{t}=K_{t}-K_{t-1}$, where $K_{t}$ is net stock from spendable earnings in year $t$ (col.3)
Net capital accumulation (NCA):
From gross earnings: $N C A_{t}=K_{t}-K_{t-1} \frac{P_{t, e n d}}{P_{t-1, e n d}}$,
where $K_{t}$ is net stock from gross earnings in year $t(c o l .2)$ and $P_{t, \text { end }}$ is as defined in note 1 to the text.
From spendable earnings: where $K_{t}$ is net stock in year $t$ calculated from spendable earnings (col. 3), otherwise similar to NCA for gross earnings.

## Table 5.39

To obtain net stocks of human capital, we assumed a fifty-year service life and used gross investment figures from 1894 to 1969 to apply a perpetual inventory method with straight-line depreciation. The underlying data are from Kendrick [3, table B-5]-total gross investment (human tangibles and nontangibles) in 1958 dollars ( $I_{t}$ ) and Kendrick [3, table B-17]-total gross stocks in 1958 dollars $\left(G_{t}\right)$, for the years 1929 to 1969 . For 1894 to 1919 , gross investment was obtained from the assumed identity $G_{t}-G_{t-1} \equiv I_{t}-I_{t-50}$. Hence,

$$
I_{t-50} \equiv G_{t-1}+I_{t}-G_{t}, \text { for } t=1944 \text { to } 1969
$$

For the years 1920 to 1928 , the following interpolation was used:

$$
I_{t}=I_{1919} \frac{I_{1929}}{I_{1919}} \cdot \mathbf{1 ( t - 1 9 1 9 )} 1919<t<1929
$$

For 1929 to 1969, Kendrick [3, table 11] was used. Applying the perpetual inventory method with straight-line depreciation, we obtain net stocks and depreciation for the years 1946 to 1969. Net investment is then the difference between gross investment and depreciation for each year. These are then converted to current dollars using an implicit human capital total gross investment deflator, calculated from Kendrick's cur-rent- and constant-dollar figures for gross investment in human capital. Gross and net revaluations then follow as per equations (1) and (2) in the text. Net capital accumulation $=$ net investment + net revaluations.

Table 5.40
Table 5.39 converted to 1969 dollars using implicit price deflators calculated from Kendrick's [3] current- and constant-dollar figures for gross investment in human capital.

## Table 5.41

Net capital accumulation $=$ net investment + net revaluations
Nonhuman capital
Net investment from table 5.1, col. 3
Net revaluations from table 5.1, col. 5
Human capital
Net investment from table 5.40, col. 5
Net revaluations from table 5.39 , col. 7
Total capital $=$ nonhuman capital + human capital

## Table 5.42

Table 5.41 converted to 1969 dollars using the implicit price deflator for fixed investment on nonhuman capital, and for gross investment in hu-
man capital, as used for table 5.40 on human capital. For these deflators, see table 5.58 .

Table 5.43, from table 5.35 and table 5.39

## Table 5.44, Net Capital Accumulation of Tangible Assets, Current Dollars

Net capital accumulation $=$ net investment + net revaluations.
Net investment for households, noncorporate, nonfinancial corporations, private financial, and government sectors equals the acquisition of assets net of depreciation charges when applicable, plus the reduction in liabilities summed for all assets and liabilities appearing in tables 5.47, $49,51,53$, and 55 , respectively. Net revaluations for these respective sectors relates to net worth and equals the difference between net revaluations on total assets and on total liabilities as shown in the separate sector tables.

## Table 5.45, Reproducible Assets, Current Dollars

Figures for household, noncorporate, nonfinancial corporations, private financial, and government sectors, respectively, from tables $5.47,49,51$, 53 , and 55.

## Table 5.46, Reproducible Assets, 1972 Dollars

Figures for household, noncorporate, nonfinancial corporations, private financial, and government sectors, respectively, from tables $5.48,50,52$, 54 , and 56.

## Notes

1. When quarterly investment data are available we may use

$$
\frac{P_{t}, \text { end }}{4} \sum_{i=1}^{4} \frac{I N_{t, i}}{P_{t, i}} \text { instead of } \frac{P_{t}, \text { end }}{P_{t}} I N_{t}
$$

where $I N_{t, i}$ is net investment of the $i$ th quarter, at annual rates, and $P_{t, i}$ is the general price deflator of the $i$ th quarter. We have taken as the general price deflator at the end of the year $t$,

$$
P_{t} \text { end }=\left(P_{t+1,1}+P_{t, 4}\right) / 2
$$

where $P_{t+1,1}$ is the first-quarter deflator of the year $t+1$ and $P_{t .4}$ is the fourthquarter deflator of the year $t$. With quarterly price deflators available but investment only annual, we have used annual investment, $I N_{t}$, instead of $I N_{t, i}$, so that the final term in (2) was generally taken as

$$
\frac{P_{t}, \text { end }}{4} \sum_{i=1}^{4} \frac{I N_{t}}{P_{t, i}} .
$$

4. To be published in The Review of Income and Wealth, 1979.
5. Current-dollar estimates are generally to be found in odd-numbered tables, estimates in 1972 dollars in even-numbered tables.
6. Calculated from table 5.1. Net worth at the end of 1945 equals net worth at the end of 1946 minus net investment and gross revaluations of 1946.
7. Reflecting in large part depreciation and disposal of military equipment after World War II and the large federal government deficits of 1975 to 1977.
8. The Kendrick-derived net capital accumulation of $\$ 1,864$ billion from 1948 to 1969 compares remarkably with the present value total net accumulation of $\$ 1,925$ billion over the same period taken from table 5.38. The latter deals only with male earnings, however. Other conceptual or definitional problems aside, it would apparently take a higher rate of discount than $7.5 \%$ to equate the present value of all human capital with its supply price.
9. Summaries of net revaluations of reproducible assets, land and total tangibles by sector are shown in tables 5.45 and 5.46 .

## Comment Martin J. Bailey

The Eisner paper provides a significant addition to the stock of wellconstructed data on income and wealth; future scholars will use it fruitfully. Moreover, the proposal to include capital gains in national income is well taken; I liked it when I first proposed it, and I like it now, except for those capital gains that are due to changes in the real rate of interest. Therefore my comments involve comparatively minor points.

The reason it is important to measure the capital gains component of income is that tax laws and traditional accounting practices have led to the reporting of true economic income as capital gains. Depreciation practices, charging off of research and development and similar expenses against current income, and related practices now lead to the systematic understatement of income in the national accounts. Whether

[^3]these practices merely "defer" the reporting of income or lead to the conversion of ordinary income into reported capital gains, the appropriate corrective is to add accrued capital gains to income, including accruals to market values of assets in excess of their book values.

However, additions to wealth that result from a fall in the real interest rate are not income. Permanent income does include accruals to wealth due to all other causes, because such accruals could be consumed without impairing the ability to go on consuming at the same level forever. In contrast, consuming additions to wealth that result from a fall in the interest rate would impair the ability to go on consuming at the same level. A change in wealth due to changes in the interest rate reflects a price change, not a tangible change in goods available. If one thinks that permanent income is the appropriate variable for the consumption function, these arguments settle the matter. If, instead, one thinks wealth is the appropriate variable, or that there is a wealth effect in consumption, one might find it expedient to include this type of capital gain in income, as an alternative to putting in wealth as an explicit variable. This questionable thought is the only exception I can think of to my point here. In any event, Eisner includes this type of capital gain mainly in his financial estimates, not in the tangible assets.

In listing the reasons that we mismeasure capital accumulation, Eisner might mention as a sixth reason that gross errors in our price indexes of capital goods, uncovered by Robert Gordon's work, also contribute to mismeasurement.

It was disappointing that Eisner insisted on strict use of straight-line depreciation. Coen's earlier work on this issue, among other work, suggests that different depreciation patterns are appropriate for different types of assets; various authors have found that declining balance is accurate for machinery. Although I feel diffident about asking Eisner to do more work on his data, it would be little more than a clerical task to show alternative estimates using the main candidates for depreciation.

As Eisner correctly states, there is an element of double counting in his financial estimates owing to his inclusion of capital gains within corporations without an offsetting item for increased net worth; the increased net worth he includes in household sector capital gains, as he properly should. Purely financial capital gains should net out to zero, except for real capital losses on currency issued by the Treasury. Although Eisner did not prepare his totals to produce this complete netting out, he presents the data with which the interested user can do it himself-a redeeming virtue that applies to many other possible criticisms of his procedures.

Net revaluations of tangible assets would look quite different if they could be estimated with secondhand prices rather than replacement
cost-they would have swings comparable to those in the stock market. Regrettably, it is impractical to try to construct estimates of revaluations on this basis.

In conclusion, we should appreciate the important contribution this work contains; it is valuable and useful.

## Comment J. W. S. Walton

I welcome this paper, which I regard as an important contribution to the application of macroeconomics. It is well established that the command over resources of an individual or household is affected by capital gains or losses on assets held, and the paper seeks to quantify these influences, for example, on the real income of households, in relation to the similar influences on the real income of other groups of economic entities. This seems quite compatible with preserving the identity in the conventional accounts between product and the sum of factor incomes contributing to that product. In the conventional accounting framework, consumption out of capital gains is regarded as dissaving. For the total economy, real income will vary in relation to real product only according to shifts in international transfers or in the terms of trade; but an excess of aggregate domestic use of resources over either aggregate income or aggregate product is still possible when there is an expectation of a substantial future increase in the future provision of resources domestically. [I have only to look at the number of Arabs walking around the streets of London to appreciate that consumption can be generated by an increase in either the real income or the real wealth represented by a given product.]

At a disaggregated level within the domestic economy, command over resources is further affected by the effects of changes in the buying power of the income streams arising from financial claims, particularly as the result of inflation.

The United Nations Statistical Office has produced an accounting framework, in the shape of guidelines for the compilation of national and sector balance sheets. In these a reconciliation account connects conventional incomes with the changes between opening and closing net assets. The framework, incidentally, shows separately the "net worth" of corporations, defined as their total wealth-total assets less liabilities to third parties-from which is deducted the market value of the equity interest of the proprietors, and this net worth is regarded as part of the independent wealth of the corporate sector; no double counting is there-

[^4]fore necessary. The system of valuation is broadly by market values or replacement cost rather than according to economic value, so that "goodwill" is not provided for. It is in terms of current prices and costs, so that the system leaves quite open the question to what extent the gross revaluation surplus should be regarded as spendable income or as necessary to provide for the maintenance of opening wealth.

Professor Eisner's solution to this problem is to use as a numeraire the nationally available "basket" of goods and services-the GNP deflator. I worry about the implications of using this system of estimationor any other using a general price index-upon the concept of business "income," taking this in the sense of the amount of trading surplus that is available for distribution (or, if not distributed, for internally financed capital expansion) after maintaining the "wealth" of the business. This gets to the heart of the current debate about systems of inflation accounting, in particular how to estimate what is needed to maintain the opening "wealth" of a business. Accountants have, of course, always regarded income as the growth of net assets, and the debate on how to allow for the effect of inflation on net assets reflects two rather different views of the object served by business accounts, which have been called the "equity" and the "entity" concepts.

According to the "equity" concept, in going from gross to net revaluations one would deduct from gross revaluations the amount needed to maintain the purchasing power to the shareholder of his opening stake —this is very similar to Professor Eisner's procedure. According to the "entity" concept, the shareholders' interest is regarded as stemming from the viability of the business as a going concern, so that one would initially regard the gross revaluation as a provision needed for maintenance of what has been called the "substance of the business." It is fairly readily agreed that the "substance of the business" will include physical assets (though the debate continues about whether to include monetary items, in particular monetary working capital), so that gross revaluations on fixed assets and inventories-when estimated by use of replacement cost or of the concept of "deprival" value formulated by the United Kingdom Sandilands Committee-are primarily regarded as representing funds required within the business. On this basis, net revaluations on fixed assets and inventories, in the sense of being regarded as part of the distributable surplus, will be zero or very small. However, such a systems of valuation ignores "goodwill," in the sense of the excess of the economic value (the present value of the future income stream) of a collection of assets over their current replacement cost, and evidently this excess-if it could have a value placed upon it-would rank for inclusion in net revaluations, even according to the "entity" concept. Similarly, economic value, if applied to monetary assets and liabilities, will in principle generate gross revaluation surpluses or defi-
cits, against which assessments would be required of the amounts needed for maintenance of the "substance of the business."

In considering the relationship between the aggregated conventional accounts and the more comprehensive accounts in their disaggregated form, it is instructive to look at the gross revaluations arising on inven-tories-the difference between their value at the time materials are purchased and their value at the time they are taken into the productive process. The initial position is that these revaluation surpluses are needed within the business, for example, to maintain a given relationship between the volume of materials held as stock and the volume of output. But this relationship of course varies, and, in addition, businessmen would say that "good buying" (or bad buying)-for instance, a lengthening of the pipeline of materials in successful anticipation of a rise in its price, where the gain exceeds the additional financing cost-is part of income. In Professor Eisner's framework such an element of the gross revaluations on inventories would remain in the net revaluations and could likewise be treated as part of income. It is of course quite possible in theory for a single business to be persistently successful in entrepreneurial activity of this kind-at the expense of someone else. In just the same way, pure speculative activity can generate gains, whether they are called income or capital gains, that provide command over resources to the successful speculator.

[^0]:    Robert Eisner is William R. Kenan Professor of Economics at Northwestern University.

    This paper was prepared with the critical financial support of National Science Foundation grants 72063, for the Measurement of Economic and Social Performance, and SOC77-17555, for the Distributional and Behavioral Implications of

[^1]:    Total Income Measurement. Since its presentation at the Toronto Conference in 1976 it has been updated from 1975 to 1977, and many of the statistical series have been revised on the basis of newly available data. A number of consolidated tables have been added, particularly on Martin J. Bailey's suggestion in his comment on the earlier version, to present totals without the double counting implicit in unadjusted summing of individual sectors.

    John C. Musgrave, of the Bureau of Economic Analysis of the United States Department of Commerce, and first Helen Tice, then Elizabeth Fogler of the Flow of Funds section of the Federal Reserve Board, have been invaluable guides to data and sources of unpublished tabulations. Those who have labored mightily on the mass of data collection and processing, both on and off the computer, include Marsha Courchane and René Moreno, Jeffrey Silber, Augustine Fosu, John Graham, Roy Webb, and Paul Burik. David Reishus, David Nebhut, and Emily Simons have been of key assistance in the final revisions and updating. As always, Molly Fabian has with good cheer and great skill navigated laborious typing and revisions of tables and manuscript.
