Will 21$^\text{c}$ Capitalism be as Unequal as 19$^\text{c}$ Capitalism?

Thomas Piketty
Paris School of Economics
SIE Meeting, Roma Tre, October 15$^{th}$ 2011
Will 21\(^{c}\) Capitalism be as Unequal as 19\(^{c}\) Capitalism?

- Long run distributional trends = key question asked by 19\(^{c}\) economists
- Many came with apocalyptic answers
- Ricardo-Marx: a small group in society (land owners or capitalists) will capture an ever growing share of income & wealth; no balanced development path can occur
- During 20\(^{c}\), a more optimistic consensus emerged: “growth is a rising tide that lifts all boats” (Kuznets 1953; cold war context)
• But inequality ↑ since 1970s destroyed this fragile consensus (US 1976-2007: >50% of total growth was absorbed by top 1%)
  → 19C economists raised the right questions; we need to address these questions again; we have no strong reason to believe in balanced development path
• 2007-2010 crisis also raised doubts about balanced devt path… will stock options & bonuses, or oil-rich countries, or China, or tax havens, absorb an ever growing share of world resources in 21C capitalism?
This talk: three issues

• 1. The rise of the working rich

• 2. The return of inheritance
  (Piketty, « On the Long Run Evolution of Inheritance – France 1820-2050 », QJE 2011) (r>g)

• 3. The future of global inequality
1. The Rise of the Working Rich

- Top income project: 23 countries, annual series over most of 20C. Two main findings:
  - The fall of rentiers: inequality ↓ during first half of 20C = top capital incomes hit by 1914-1945 capital shocks; did not fully recover so far (long lasting shock + progressive taxation) → no long run decline of earnings inequality; nothing to do with a Kuznets-type process
  - The rise of working rich: inequality ↑ since 1970s; mostly due to top labor incomes → what happened?
FIGURE 1
The Top Decile Income Share in the United States, 1917-2007

Income is defined as market income including realized capital gains (excludes government transfers).

Computations based on family market income including realized capital gains (before individual taxes).
Incomes are deflated using the Consumer Price Index (and using the CPI-U-RS before 1992).
Column (4) reports the fraction of total real family income growth captured by the top 1%.
For example, from 2002 to 2007, average real family incomes grew by 3.0% annually but 65% of that growth accrued to the top 1% while only 35% of that growth accrued to the bottom 99% of US families.
Figure 7A. Top 1% share: English Speaking countries (U-shaped), 1910-2005
Figure 7B. Top 1% Share: Middle Europe and Japan (L-shaped), 1900-2005
Why are US working rich so rich?

• Hard to account for observed variations with a pure technological, marginal-product story
• One popular view: US today = working rich get their marginal product (globalization, superstars); Europe today (& US 1970s) = market prices for high skills are distorted downwards (social norms, etc.)

→ very naïve view of the top labor market…

& very ideological: we have zero evidence on the marginal product of top executives; it could well be that prices are distorted upwards…
Another view: grabbing hand model = marginal products are unobservable; top executives have an obvious incentive to convince shareholders & subordinates that they are worth a lot; no market convergence because constantly changing corporate & job structure (& costs of experimentation)→when pay setters set their own pay, there’s no limit to rent extraction... unless confiscatory tax rates at the very top (memo: US top rate (1m$+) 1932-1980 = 82%) (no more fringe benefits than today)
2. The return of inheritance

- **Distributional issue**: wealth inequality ↓ during 20C.. but not that much: in 2010, top 10% wealth share ≈ 70-75% (US), 60-65% (EU), vs ≈ 80-90% around 1900 & in 19C

- **Macro issue**: aggregate inheritance flow vs aggregate labor income: much larger historical variations → long lasting « human K » illusion
  → this is the issue explored in « On the Long Run Evolution of Inheritance – France 1820-2050 », WP PSE 2010, forth. QJE 2011
Figure 1: Annual inheritance flow as a fraction of national income, France 1820-2008

- Economic flow (computed from national wealth estimates, mortality tables and observed age-wealth profiles)
- Fiscal flow (computed from observed bequest and gift tax data, inc. tax exempt assets)
What this paper does

• Documents this fact; develops a simple theoretical model explaining & reproducing this fact

• **Main lesson:** with \( r > g \), inheritance is bound to dominate new wealth; the past eats up the future

\[ r = \text{rate of return to capital} = \frac{\text{(net profits + rents)}}{\text{(net financial + real estate wealth)}}; \ g = \text{growth rate} \ (g+n) \]

• **Intuition:** with \( r > g \) & \( g \) low (say \( r=4\%-5\% \) vs \( g=1\%-2\% \)), wealth coming from the past is being capitalized faster than growth; heirs just need to save a fraction \( \frac{g}{r} \) of the return to inherited wealth \( \rightarrow b_y = \frac{\beta}{H} \)

\( \rightarrow \) with \( \beta=600\% \) & \( H=30 \), then \( b_y = 20\% \)

• It is only in countries & time periods with \( g \) exceptionally high that self-made wealth dominates inherited wealth (OECD in 1950s-70s or China today)
Figure 9: Observed vs simulated inheritance flow B/Y, France 1820-2100

- Observed series
- Simulated series (2010-2100: g=1.7%, (1-t)r=3.0%)
- Simulated series (2010-2100: g=1.0%, (1-t)r=5.0%)
Back to distributional analysis: macro ratios determine who is the dominant social class

- 19C: top successors dominate top labor earners → rentier society (Balzac, Jane Austen, etc.)
- For cohorts born in 1910s-1950s, inheritance did not matter too much → labor-based, meritocratic society
- But for cohorts born in the 1970s-1980s & after, inheritance matters a lot → 21C closer to 19C rentier society than to 20C merit society
- The rise of human capital & meritocracy was an illusion .. especially with a labor-based tax system
- Two (quasi-)illusions: human K didn’t replace financial K; war of ages didn’t replace war of classes
3. The future of global inequality

- **Around 1900-1910**: Europe owned the rest of the world; net foreign wealth of UK or France >100% of their national income (>50% of the rest-of-the-world capital stock)
- **Around 2050**: will the same process happen again, but with China instead of Europe?
• Assume global convergence in per capita output Y & in capital intensity K/Y
• With large differences in population & fully integrated K markets & high world rate of return r (low K taxes)
Then moderate differences in savings rate (say, s=20% in China vs s=10% in Europe+US, due to bigger pay-as-you-go pensions in Old World, traumatized by past financial crashes) can generate v. large net foreign asset positions → under these assumptions, China might own a large part of the world by 2050
Likely policy response in the West: K controls, public ownership of domestic firms, etc.

But this is not the most likely scenario: a more plausible scenario is that global billionaires (located in all countries... and particularly in tax havens) will own a rising share of global wealth.

A lot depends on the net-of-tax global rate of return r on large diversified portfolios.

If r=5%-6% in 2010-2050 (=what we observe in 1980-2010 for large Forbes fortunes, or Abu Dhabi sovereign fund, or Harvard endowment), then global divergence is very likely.
• Both scenarios can happen
• But the «global billionaires own the world» scenario is more likely than the «China own the world» scenario
• And it is also a lot harder to cope with: we’ll need a lot of international policy coordination; without a global crackdown on tax havens & a coordinated world wealth tax on the global rich, individual countries & regions will keep competing to attract billionaires, thereby exacerbating the trend
• Free, untaxed world K markets can easily lead to major imbalances & global disasters
What have we learned?

• A world with $g$ low & $r > g$ is gloomy for workers with zero inherited wealth
  … especially if global tax competition drives capital taxes to 0%
  … especially if top labor incomes take a rising share of aggregate labor income
  → let’s unite to tax capital & top labor; otherwise the future looks gloom…

• A world with $g=1-2\%$ (=long-run world technological frontier) is not very different from a world with $g=0\%$ (Marx-Ricardo)
• More efficient markets won’t help…
• The more efficient the markets, the sharper the capital vs labor distinction; with highly developed k markets, any dull successor can get a high rate of return
• \( r > g \) = the true evil law of capitalism
  = nothing to do with market imperfections
• Standard model: \( r = \delta + \sigma g > g \) (Golden rule)
• The important point about capitalism is that \( r \) is large (\( r > g \rightarrow \) tax capital, otherwise society is dominated by rentiers), volatile and unpredictable (crisis)

Computing inheritance flows: simple macro arithmetic

\[
B_t/Y_t = \mu_t \ m_t \ W_t/Y_t
\]

- \(W_t/Y_t\) = aggregate wealth/income ratio
- \(m_t\) = aggregate mortality rate
- \(\mu_t\) = ratio between average wealth of decedents and average wealth of the living (= age-wealth profile)

→ The U-shaped pattern of inheritance is the product of three U-shaped effects

Figure 5: Inheritance flow vs mortality rate in France, 1820-2008

- □ Annual inheritance flow as a fraction of aggregate private wealth
- ■ Adult mortality rate (20-yr-old & over)
Steady-state inheritance flows

• Standard models: \( r = \theta + \sigma g = \alpha g/s \ (> g) \)
• Everybody becomes adult at age \( A \), has one kid at age \( H \), inherits at age \( I \), and dies at age \( D \) → \( I = D - H \), \( m = 1/(D-A) \)
• Dynastic or class saving: \( \mu = (D-A)/H \)
  → \( b_y = \mu \ m \ \beta = \beta/H \)

• **Proposition**: As \( g \rightarrow 0 \), \( b_y \rightarrow \beta/H \)
